# Regularized Least Squares 

9.520 Class 04, 21 February 2006

Ryan Rifkin

## Plan

- Introduction to Regularized Least Squares
- Computation: General RLS
- Large Data Sets: Subset of Regressors
- Computation: Linear RLS

## Regression

We have a training set $S=\left\{\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right), \ldots,\left(\mathbf{x}_{\ell}, \mathbf{y}_{\ell}\right)\right\}$. The $\mathbf{y}_{i}$ are real-valued. The goal is to learn a function $f$ to predict the $y$ values associated with new observed $x$ values.

## Our Friend Tikhonov Regularization

We pose our regression task as the Tikhonov minimization problem:

$$
f=\arg \min _{f \in \mathcal{H}} \frac{1}{2} \sum_{i=1}^{\ell} V\left(f\left(\mathbf{x}_{i}\right), \mathbf{y}_{i}\right)+\frac{\lambda}{2}\|f\|_{K}^{2}
$$

To fully specify the problem, we need to choose a loss function $V$ and a kernel function $K$.

## The Square Loss

For regression, a natural choice of loss function is the square loss $V(f(\mathrm{x}), y)=(f(\mathrm{x})-y)^{2}$.

## Substituting In The Square Loss

Using the square loss, our problem becomes

$$
f=\arg \min _{f \in \mathcal{H}} \frac{1}{2} \sum_{i=1}^{\ell}\left(f\left(x_{i}\right)-y_{i}\right)^{2}+\frac{\lambda}{2}\|f\|_{K}^{2}
$$

## The Return of the Representer Theorem

Theorem. The solution to the Tikhonov regularization problem

$$
\min _{f \in \mathcal{H}} \frac{1}{2} \sum_{i=1}^{\ell} V\left(y_{i}, f\left(\mathbf{x}_{i}\right)\right)+\frac{\lambda}{2}\|f\|_{K}^{2}
$$

can be written in the form

$$
f=\sum_{i=1}^{\ell} c_{i} K\left(\mathbf{x}_{i}, \cdot\right)
$$

This theorem is exceedingly useful - it says that to solve the Tikhonov regularization problem, we need only find the best function of the form $f=\sum_{i=1}^{\ell} c_{i} \mathbf{K}\left(\mathbf{x}_{i}\right)$. Put differently, all we have to do is find the $c_{i}$.

## Applying the Representer Theorem, I

NOTATION ALERT!!! We use the symbol $K$ for the kernel function, and boldface $\mathbf{K}$ for the $\ell$-by- $\ell$ matrix:

$$
\mathbf{K}_{i j} \equiv K\left(x_{i}, x_{j}\right)
$$

Using this definition, consider the output of our function

$$
f=\sum_{i=1}^{\ell} c_{i} K\left(\mathbf{x}_{i}, \cdot\right)
$$

at the training point $x_{j}$ :

$$
\begin{aligned}
f\left(\mathbf{x}_{j}\right) & =\sum_{i=1}^{\ell} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) c_{i} \\
& =(\mathbf{K c})_{j}
\end{aligned}
$$

## Using the Norm of a "Represented"

 FunctionA function in the RKHS with a finite representation

$$
f=\sum_{i=1}^{\ell} c_{i} K\left(\mathbf{x}_{i}, \cdot\right)
$$

satisfies

$$
\begin{aligned}
\|f\|_{k}^{2} & =\left\langle\sum_{i=1}^{\ell} c_{i} K\left(\mathbf{x}_{i}, \cdot\right), \sum_{j=1}^{\ell} c_{j} K\left(\mathbf{x}_{j}, \cdot\right)\right\rangle \\
& =\sum_{i=1}^{\ell} \sum_{j=1}^{\ell} c_{i} c_{j}\left\langle K\left(\mathbf{x}_{i}, \cdot\right), K\left(\mathbf{x}_{j}, \cdot\right)\right\rangle \\
& =\sum_{i=1}^{\ell} \sum_{j=1}^{\ell} c_{i} c_{j} K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right) \\
& =\mathbf{c}^{t} \mathbf{K} \mathbf{c}
\end{aligned}
$$

## The RLS Problem

Substituting, our Tikhonov minimization problem becomes:

$$
\min _{\mathbf{c} \in \mathbb{R}^{\ell}} \frac{1}{2}\|\mathbf{K c}-\mathbf{y}\|_{2}^{2}+\frac{\lambda}{2} \mathbf{c}^{T} K \mathbf{c} .
$$

## Solving the Least Squares Problem, I

We are trying to minimize

$$
g(c)=\frac{1}{2}\|\mathbf{K c}-\mathbf{y}\|_{2}^{2}+\frac{\lambda}{2} \mathbf{c}^{T} K \mathbf{c}
$$

This is a convex, differentiable function of $c$, so we can minimize it simply by taking the derivative with respect to $c$, then setting this derivative to 0 .

$$
\frac{\partial g(c)}{\partial c}=\mathbf{K}(\mathbf{K c}-\mathbf{y})+\lambda \mathbf{K c}
$$

## Solving the Least Squares Problem, II

Setting the derivative to 0 ,

$$
\begin{aligned}
& \frac{\partial g(c)}{\partial c}=\mathbf{K}(\mathbf{K} \mathbf{c}-\mathbf{y})+\lambda \mathbf{K} \mathbf{c}=\mathbf{0} \\
\rightarrow \quad & \mathbf{K}(\mathbf{K} \mathbf{c})+\lambda \mathbf{K} \mathbf{c}=\mathbf{K} \mathbf{y} \\
" \rightarrow \prime & \mathbf{K} \mathbf{c}+\lambda \mathbf{c}=\mathbf{y} \\
\rightarrow & (\mathbf{K}+\lambda I) \mathbf{c}=\mathbf{y} \\
\rightarrow & \mathbf{c}=(\mathbf{K}+\lambda I)^{-1} \mathbf{y}
\end{aligned}
$$

The matrix $\mathbf{K}+\lambda I$ is positive definite and will be wellconditioned if $\lambda$ is not too small.

## Leave-One-Out Values

Recalling that $S=\left\{\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right), \ldots,\left(\mathbf{x}_{\ell}, \mathbf{y}_{\ell}\right)\right\}$, we define $f_{S}$ to be the solution to the RLS problem with training set $S$. We define

$$
\begin{aligned}
S^{i} & =\left\{S \backslash \mathbf{x}_{i}\right\} \\
& =\left\{\left(\mathbf{x}_{1}, \mathbf{y}_{1}\right), \ldots,\left(\mathbf{x}_{i-1}, \mathbf{y}_{i-1}\right),\left(\mathbf{x}_{i+1}, \mathbf{y}_{i+1}\right), \ldots,\left(\mathbf{x}_{\ell}, \mathbf{y}_{\ell}\right)\right\}
\end{aligned}
$$

the training set with the $i$ th point removed.

We call $f_{S^{i}}\left(\mathbf{x}_{i}\right)$ the $i$ th LOO value, and $\mathbf{y}_{i}-f_{S^{i}}\left(\mathbf{x}_{i}\right)$ the $i$ th LOO error. Let LOOV and LOOE be vectors whose $i$ th entries are the $i$ th LOO value and error.

Key Intuition: if $\|L O O E\|$ is small, we will generalize well.

## The Leave-One-Out Formula

Remarkably, for RLS, there is a closed form formula for $L O O E$. Defining $\mathbf{G}(\lambda)=(\mathbf{K}+\lambda I)^{-1}$, we have:

$$
\begin{aligned}
L O O E & =\frac{\mathbf{G}^{-1} \mathbf{y}}{\operatorname{diag}\left(\mathbf{G}^{-1}\right)} \\
& =\frac{\mathbf{c}}{\operatorname{diag}\left(\mathbf{G}^{-1}\right)}
\end{aligned}
$$

Proof: Later, Blackboard.

## Computing: Naive Approach

Suppose I want to minimize $\|L O O E\|$, testing $p$ different values of $\lambda$.

I form $\mathbf{K}$, which takes $O\left(n^{2} d\right)$ time (I assume $d$-dimensional data and linear-time kernels throughout).

For each $\lambda, \mathrm{I}$ form $\mathbf{G}, \mathrm{I}$ form $\mathrm{G}^{-1}\left(O\left(n^{3}\right)\right.$ time $)$, and compute $\mathbf{c}=\mathbf{G}^{-1} y$ and $\operatorname{diag}\left(\mathbf{G}^{-1}\right)$.

Over $p$ values of $\lambda$, I will pay $O\left(p n^{3}\right)$ time.

We can do much better...

## Computing: Eigendecomposing K

We form the eigendecomposition $\mathbf{K}=Q \wedge Q^{t}$, where $\wedge$ is diagonal with $\Lambda_{i i} \geq 0$ and $Q Q^{t}=I$.

Key point:

$$
\begin{aligned}
\mathbf{G} & =\mathbf{K}+\lambda I \\
& =Q \wedge Q^{t}+\lambda I \\
& =Q(\wedge+\lambda I) Q^{t}
\end{aligned}
$$

and $\mathrm{G}^{-1}=Q(\Lambda+\lambda I)^{-1} Q^{t}$.

Forming the eigendecomposition takes $O\left(n^{3}\right)$ time (in practice).

## Computing c and $L O O E$ efficiently

$$
\begin{aligned}
c(\lambda) & =\mathbf{G}(\lambda)^{-1} \mathbf{y} \\
& =Q(\Lambda+\lambda I)^{-1} Q^{t} \mathbf{y} \\
\mathbf{G}_{i j}^{-1} & =\left(Q(\Lambda+\lambda I)^{-1} Q^{t}\right)_{i j} \\
& =\sum_{k=1}^{n} \frac{Q_{i k} Q_{j k}}{\Lambda_{k k}+\lambda}
\end{aligned}
$$

Given the eigendecomposition, I can compute $\mathbf{c}, \operatorname{diag}\left(\mathbf{G}^{-1}\right)$, and $L O O E$ in $O\left(n^{2}\right)$ time. Over $p$ values of $\lambda$, I pay only $O\left(n^{3}+p n^{2}\right)$. If $p<n$, searching for a good $\lambda$ is effectively free!

## Nonlinear RLS, Suggested Approach

- 1. Form the eigendecomposition $\mathbf{K}=Q \wedge Q^{t}$.
- 2. For each value of $\lambda$ over a logarithmically spaced grid, compute $c=Q(\Lambda+\lambda I)^{-1} Q^{t} \mathbf{y}$ and $\operatorname{diag}\left(\mathbf{G}^{-1}\right)$ using the formula for the last slide. Form $L O O E$, a vector whose $i$ th entry is $\frac{\mathbf{c}_{i}}{\operatorname{diag}\left(\mathrm{G}^{-1}\right)_{i}}$.
- 3. Choose the $\lambda$ that minimizes $\|L O O E\|$ in some norm (I use $L_{2}$ ).
- 4. Given that $c$, regress a new test point $x$ with $f(x)=$ $\sum_{i} \mathbf{c}_{i} K\left(\mathbf{x}_{i}, x\right)$.

## Limits of RLS

RLS has proved very accurate. There are two computational problems:

- Training: We need $O\left(n^{2}\right)$ space (to store $\mathbf{K}$ ), and $O\left(n^{3}\right)$ time (to eigendecompose $\mathbf{K}$ )
- Testing: Testing a new point $x$ takes $O(n d)$ time to compute the $n$ kernel products in $f(x)=\sum_{i} K\left(x, \mathbf{x}_{i}\right)$.

Next class, we will see that an SVM has a sparse solution, which gives us large constant factor (but important in practice!) improvements for both the training and testing problems.

Can we do better, sticking with RLS?

## First Idea: Throw Away Data

Suppose that we throw away all but $M$ of our data points, where $M \ll \ell$. Then we only need time $M^{2} d$ to form our new, smaller kernel matrix, and we only need time $O\left(M^{3}\right)$ to solve the problem. Great, isn't it?

Well, if we have too much data to begin with (say 1,000,000 points in 3 dimensions) this will work just fine. In general, we will lose accuracy.

## Subset of Regressors

Suppose, instead of throwing away data, we restrict our hypothesis space further. Instead of allowing functions of the form

$$
f(x)=\sum_{i=1}^{\ell} \mathbf{c}_{i} K\left(\mathbf{x}_{i}, x\right)
$$

we only allow

$$
f(x)=\sum_{i=1}^{M} \mathbf{c}_{i} K\left(\mathbf{x}_{i}, x\right)
$$

where $M \ll \ell$. In other words, we only allow the first $M$ points to have non-zero $c_{i}$. However, we still measure the loss at all $\ell$ points.

## Subset of Regressors, Cont'd

Suppose we define $\mathbf{K}_{M M}$ to be the kernel matrix on just the $M$ points we're using to represent our function, and $\mathbf{K}_{M L}$ to be the kernel product between those $M$ points and the entire dataset, we can derive (homework) that the minimization problem becomes:

$$
\left(\mathbf{K}_{M L} \mathbf{K}_{L M}+\lambda \mathbf{K}_{M M}\right) \mathbf{c}=\mathbf{K}_{M L} y
$$

which is again an $M$-by- $M$ system.

Various authors have reported good results with this or similar, but the jury is still out (class project!). Sometimes called Rectangular Method.

## $\lambda$ is Still Free

To solve

$$
\left(\mathbf{K}_{M L} \mathbf{K}_{L M}+\lambda \mathbf{K}_{M M}\right) \mathbf{c}=\mathbf{K}_{M L} y
$$

consider a Cholesky factorization $\mathbf{K}_{M M}=G G^{t}$ :

$$
\begin{aligned}
& \left(\mathbf{K}_{M L} \mathbf{K}_{L M}+\lambda \mathbf{K}_{M M}\right) \mathbf{c}=\mathbf{K}_{M L} y \\
\rightarrow & \left(\mathbf{K}_{M L} \mathbf{K}_{L M}+\lambda G G^{t}\right) \mathbf{c}=\mathbf{K}_{M L} y \\
\rightarrow & \left(\mathbf{K}_{M L} \mathbf{K}_{L M}+\lambda G G^{t}\right) G^{-t} G^{t} \mathbf{c}=\mathbf{K}_{M L} y \\
\rightarrow & \left(\mathbf{K}_{M L} \mathbf{K}_{L M} G^{-t}+\lambda G\right) G^{t} \mathbf{c}=\mathbf{K}_{M L} y \\
\rightarrow & G\left(G^{-1} \mathbf{K}_{M L} \mathbf{K}_{L M} G^{-t}+\lambda I\right) G^{t} \mathbf{c}=\mathbf{K}_{M L} y
\end{aligned}
$$

and we use the "standard" RLS free- $\lambda$ algorithm on an eigendecomposition of $G^{-1} \mathbf{K}_{M L} \mathbf{K}_{L M} G^{-t}$.

## Linear Kernels

An important special case is the linear kernel

$$
K\left(\mathbf{x}_{i}, \mathbf{x}_{j}\right)=\mathrm{x}_{i} \cdot \mathrm{x}_{j}
$$

The solution function $f$ simplifies as:

$$
\begin{aligned}
f(x) & =\sum \mathbf{c}_{i} \mathbf{x}_{i} \cdot x \\
& =\left(\sum_{i} \mathbf{c}_{i} \mathbf{x}_{i}\right) \cdot x \\
& \equiv w^{t} \cdot x
\end{aligned}
$$

We can evaluate $f$ in time $d$ rather than $\ell d$.

This is a general property of Tikhonov regularization with a linear kernel, not related to the use of the square loss.

## Linear RLS

In the linear case, $\mathbf{K}=\mathbf{X}^{t} \mathbf{X}$ ( $\mathbf{x}_{i}$ is the $i$ th column of $\mathbf{X}$ ). Note that $w=\mathbf{X c}$.

We work with an "economy-sized SVD" $\mathbf{X}=U \Sigma V^{t}$, where $U$ is $d \times d$ orthogonal, $\Sigma$ is $d \times d$ diagonal spd, and $V$ is $n \times d$ with orthogonal columns ( $V^{t} V=I$ ).

$$
\begin{aligned}
w & =\mathbf{X}\left(\mathbf{X}^{t} \mathbf{X}+\lambda I\right)^{-1} \mathbf{y} \\
& =U \Sigma V^{t}\left(V \Sigma^{2} V^{t}+\lambda I\right)^{-1} \mathbf{y} \\
& =U \Sigma\left(\Sigma^{2}+\lambda I\right)^{-1} V^{t} \mathbf{y}
\end{aligned}
$$

We need $O\left(n d^{2}\right)$ time and $O(n d)$ memory to form the SVD.
Then we can get $w(\lambda)$ in $O\left(d^{2}\right)$ time. Very fast.

## Linear RLS, Sparse Data

Suppose that $d$, the number of dimensions, is enormous, and that $n$ is also large, but the data are sparse: each dimension has only a few non-zero entries. Example: document classification. We have dimensions for each word in a "dictionary". Tens of thousands of words, but only a few hundred appear in a given document.

## The Conjugate Gradient Algorithm

The conjugate gradient algorithm is a popular algorithm for solving linear systems. For this class, we need to know that CG is an iterative algorithm. The major operation is multiplying taking a matrix-vector product $A v$. $A$ need not be supplied explicitly.

CG is the method of choice when there is a way to multiply by $A$ "quickly".

## CG and Sparse Linear RLS

Remember, we are trying to solve

$$
\begin{aligned}
& (\mathbf{K}+\lambda I) \mathbf{c}=y \\
\rightarrow & \left(\mathbf{X}^{t} \mathbf{X}+\lambda I\right) \mathbf{c}=y
\end{aligned}
$$

$\mathbf{K}$ is too big to write down. $\mathbf{X}$ is "formally" too big, so we can't take its SVD, but it's sparse. We can use CG, because we can form the matrix vector-product $\left(\mathbf{X}^{t} \mathbf{X}+\lambda I\right) \mathbf{c}$ quickly:

$$
\left(\mathbf{X}^{t} \mathbf{X}+\lambda I\right) \mathbf{c}=\mathbf{X}^{t}(\mathbf{X} \mathbf{c})+\lambda \mathbf{c}
$$

Cost per iteration: $2 \bar{d} \ell$, where $\bar{d}$ is the average number of nonzero entries per data point.

## Square-Loss Classification

There is nothing to formally stop us for using the above algorithm for classification. By doing so, we are essentially treating our classification problem as a regression problem with $y$ values of 1 or -1 .

How well do you think this will work?
