9.71 Functional MRI of High-Level Vision

Fall 2007

Lecture 8B
Number: A Candidate "Special" Domain of Cognition

I. Understanding approximate number
- Adults
- Infants
- Animals

II. Brain basis of number:
- neuropsychological patients
- fMRI nderstanding approximate number

Understanding Number

- “animals, young infants, and adult humans possess a biologically determined, domain-specific representation of number”

- “a specific neural substrate, located in the left and right intraparietal area, is associated with knowledge of numbers and their relations (‘number sense’). The number domain is a prime example where strong evidence points to an evolutionary endowment of abstract domain-specific knowledge in the brain because there are parallels between number processing in animals and humans.”

–Dehaene, Dehaene-Lambertz & Cohen, TINS, 1998

What does “number sense” mean?

• Adults can represent large numerical magnitudes without verbal counting.

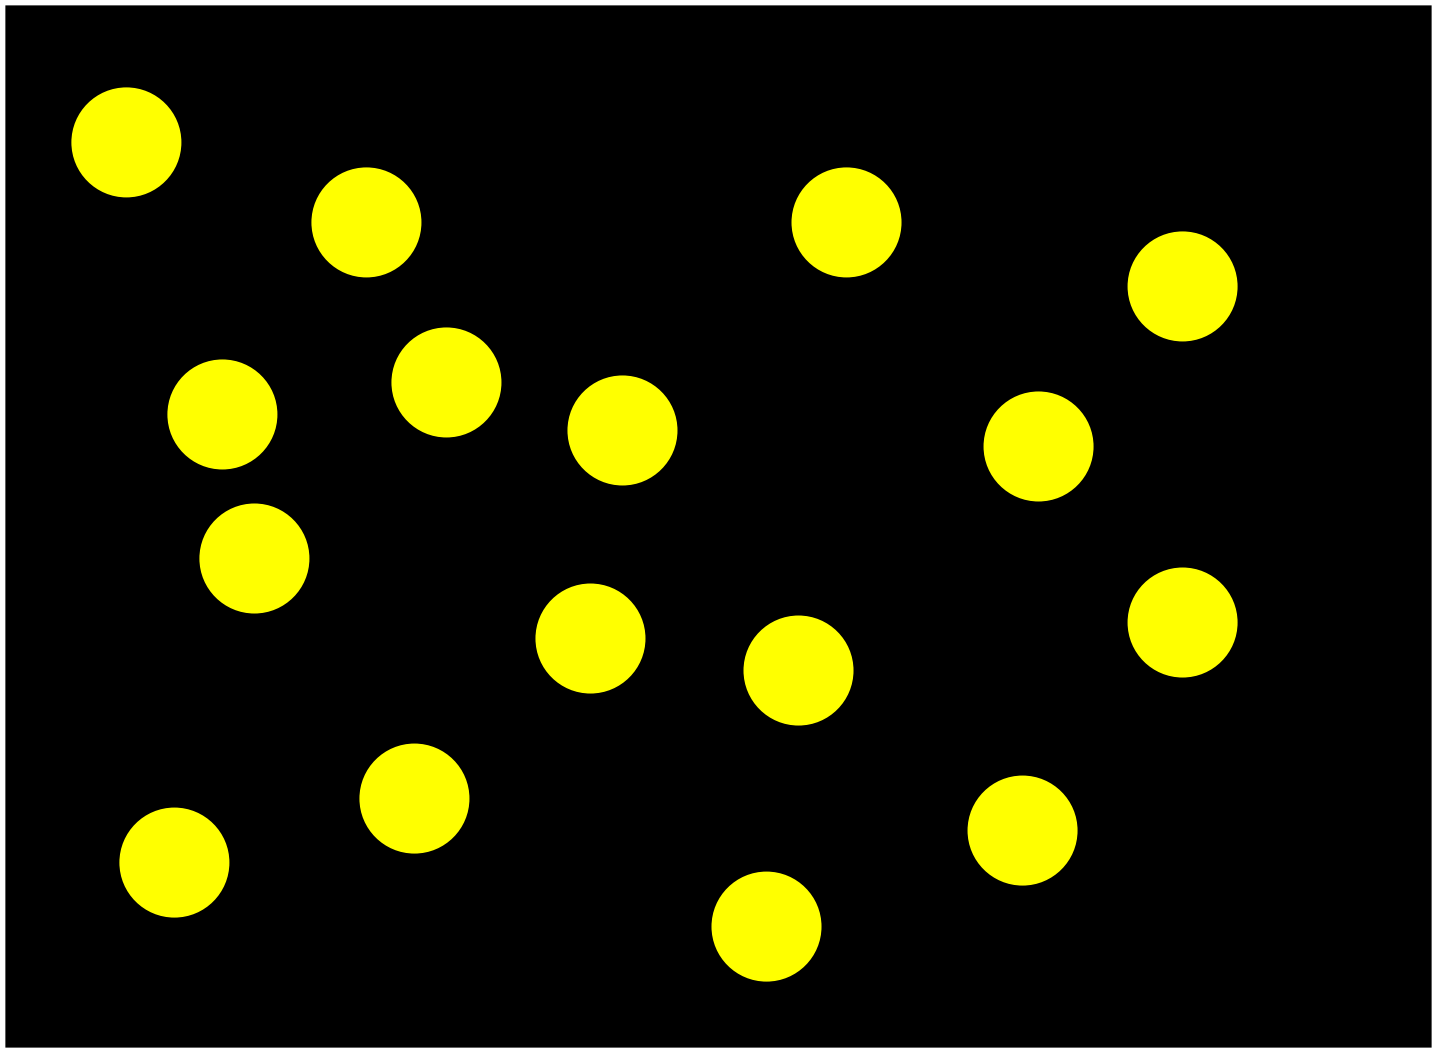
• The representations are approximate; discriminability of two numerosities depends on their ratio.

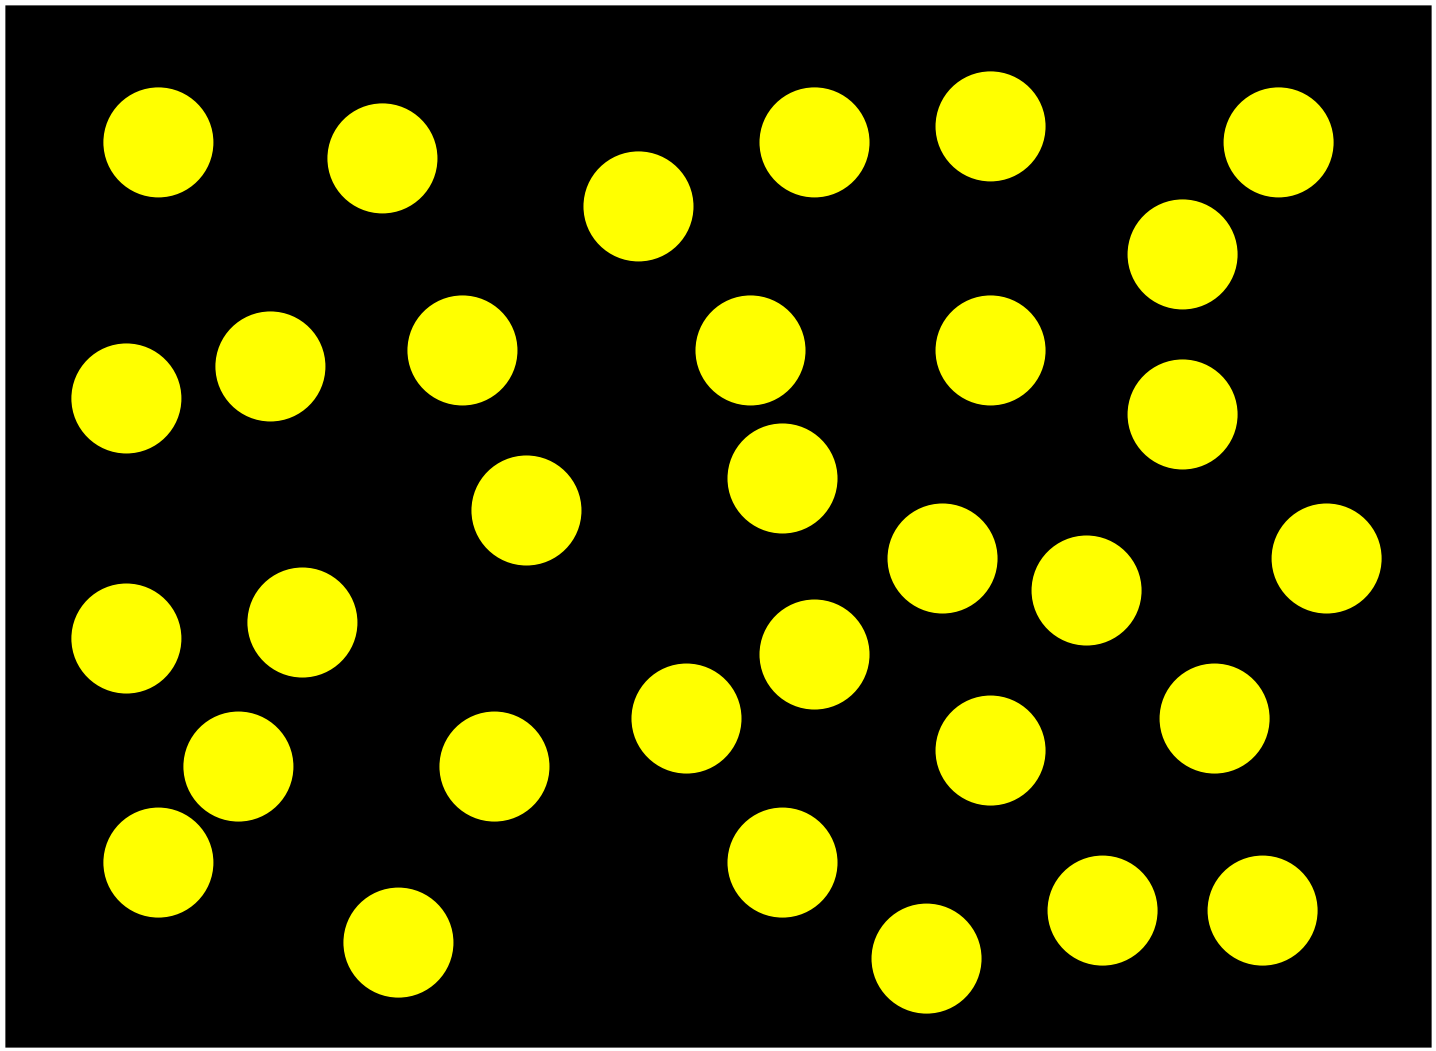
• The representations are abstract.

• The representations enter into arithmetic computations (addition).

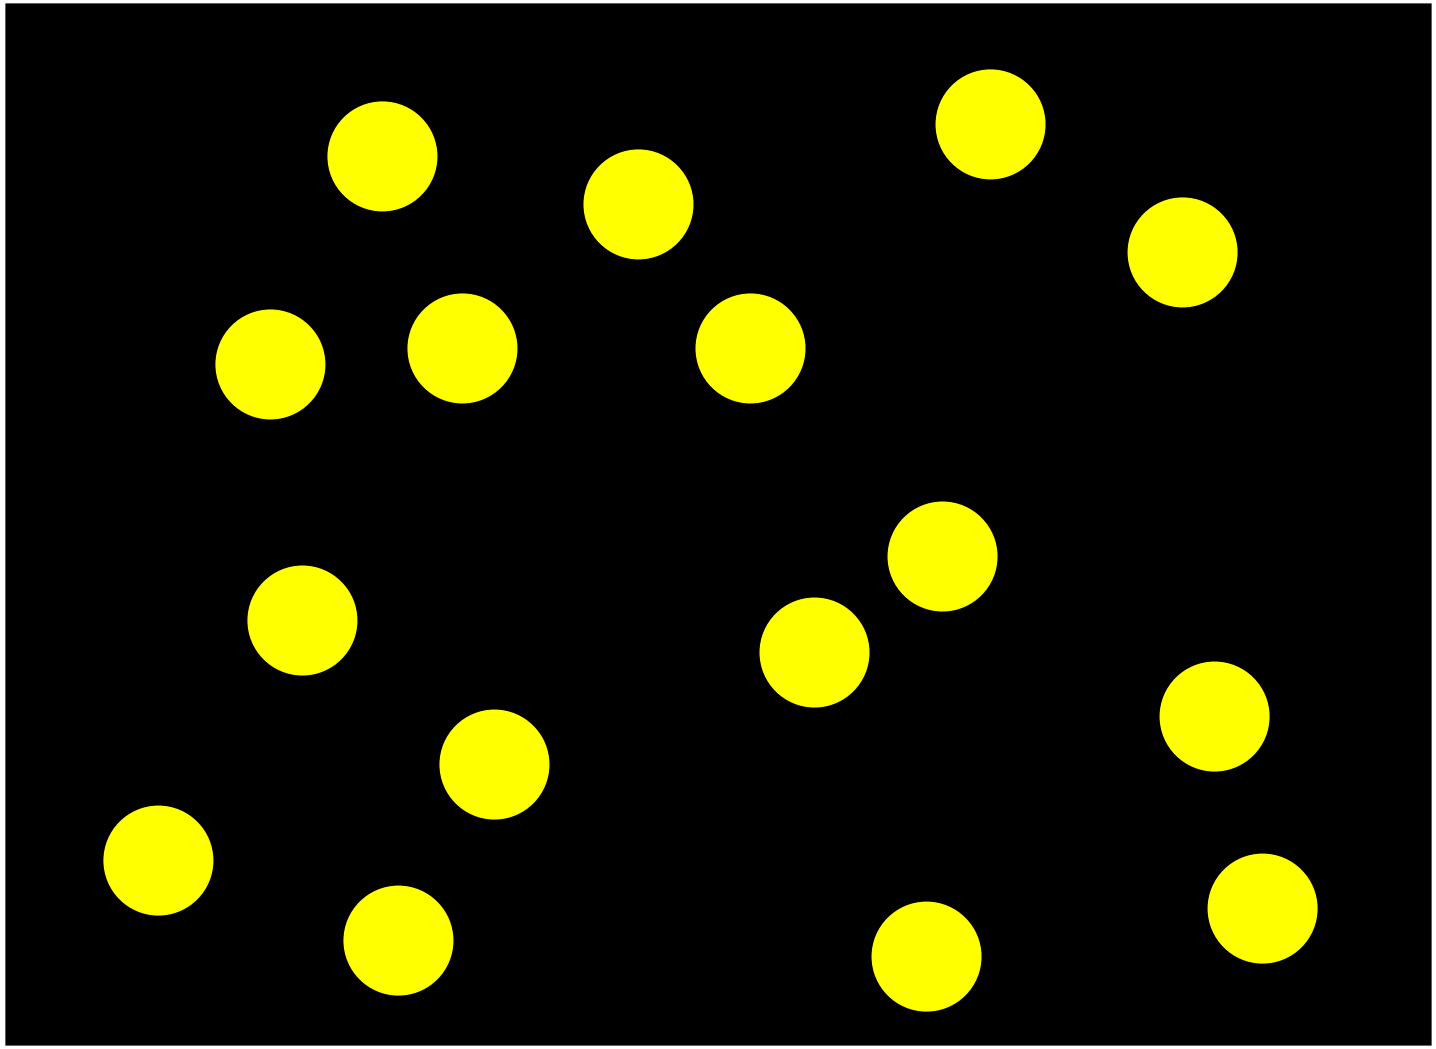
For example……

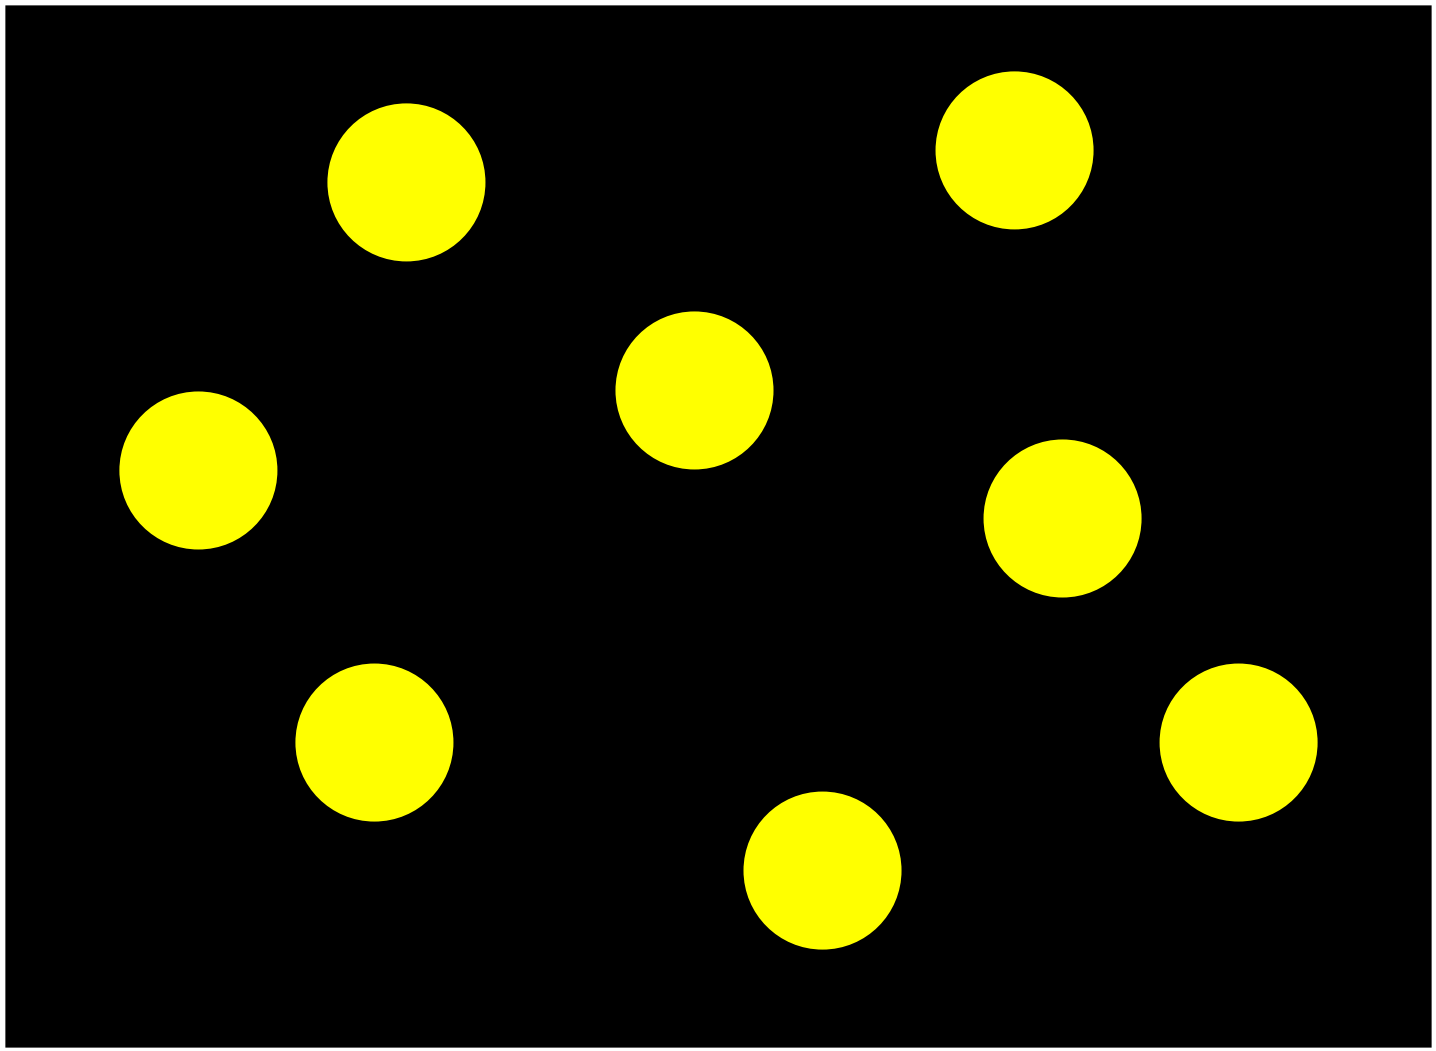
Which has more dots?



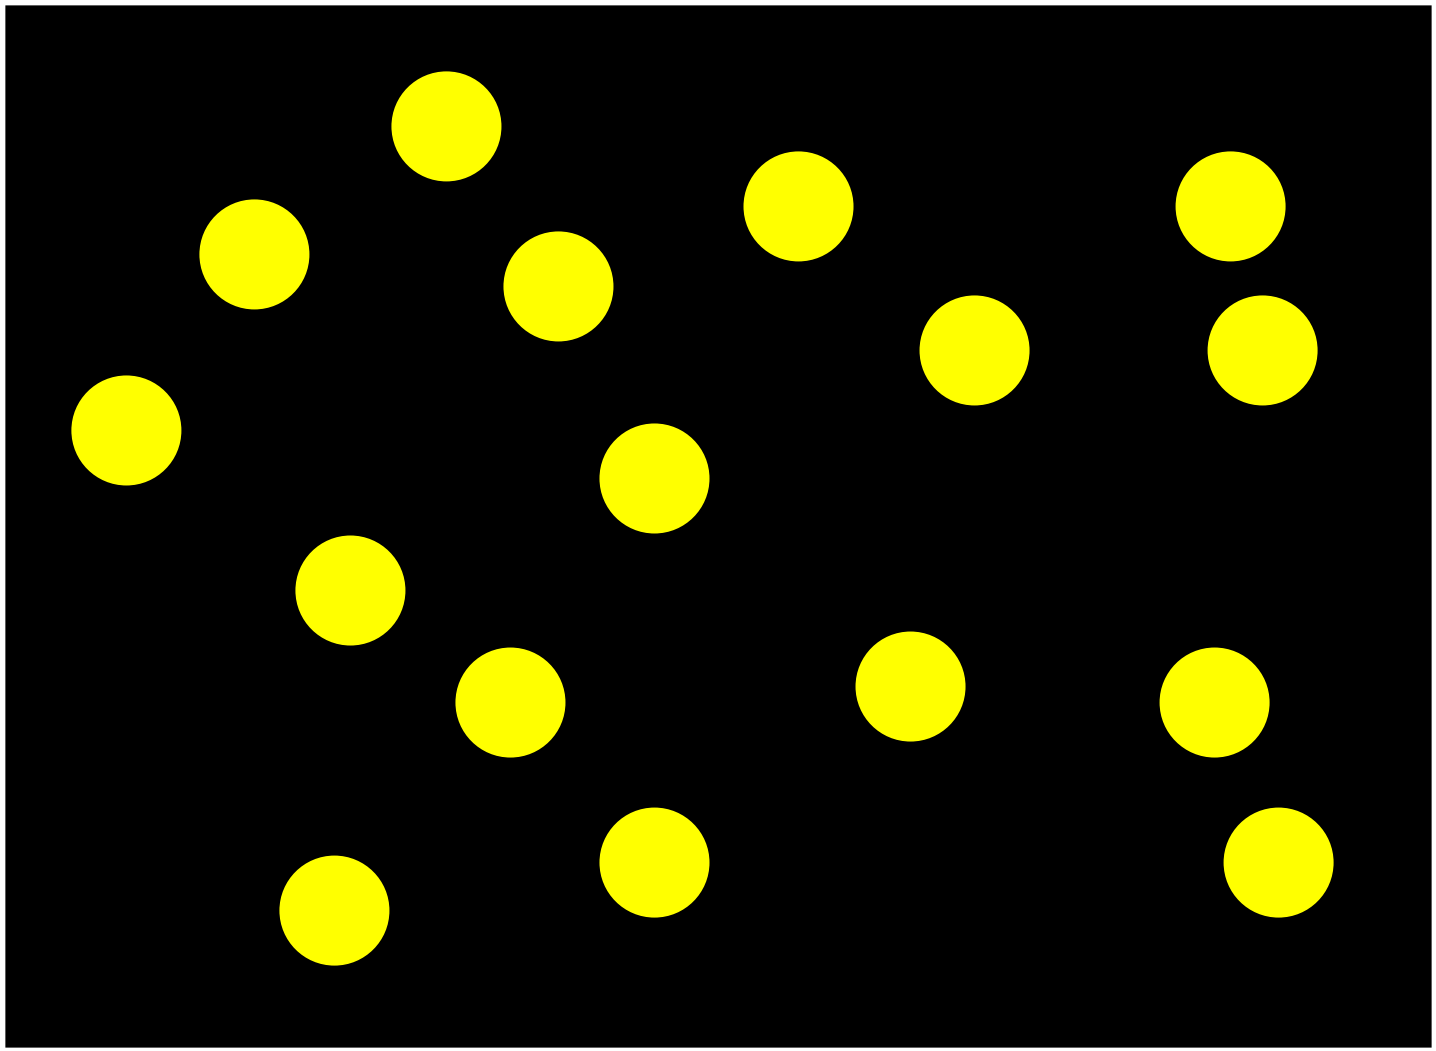


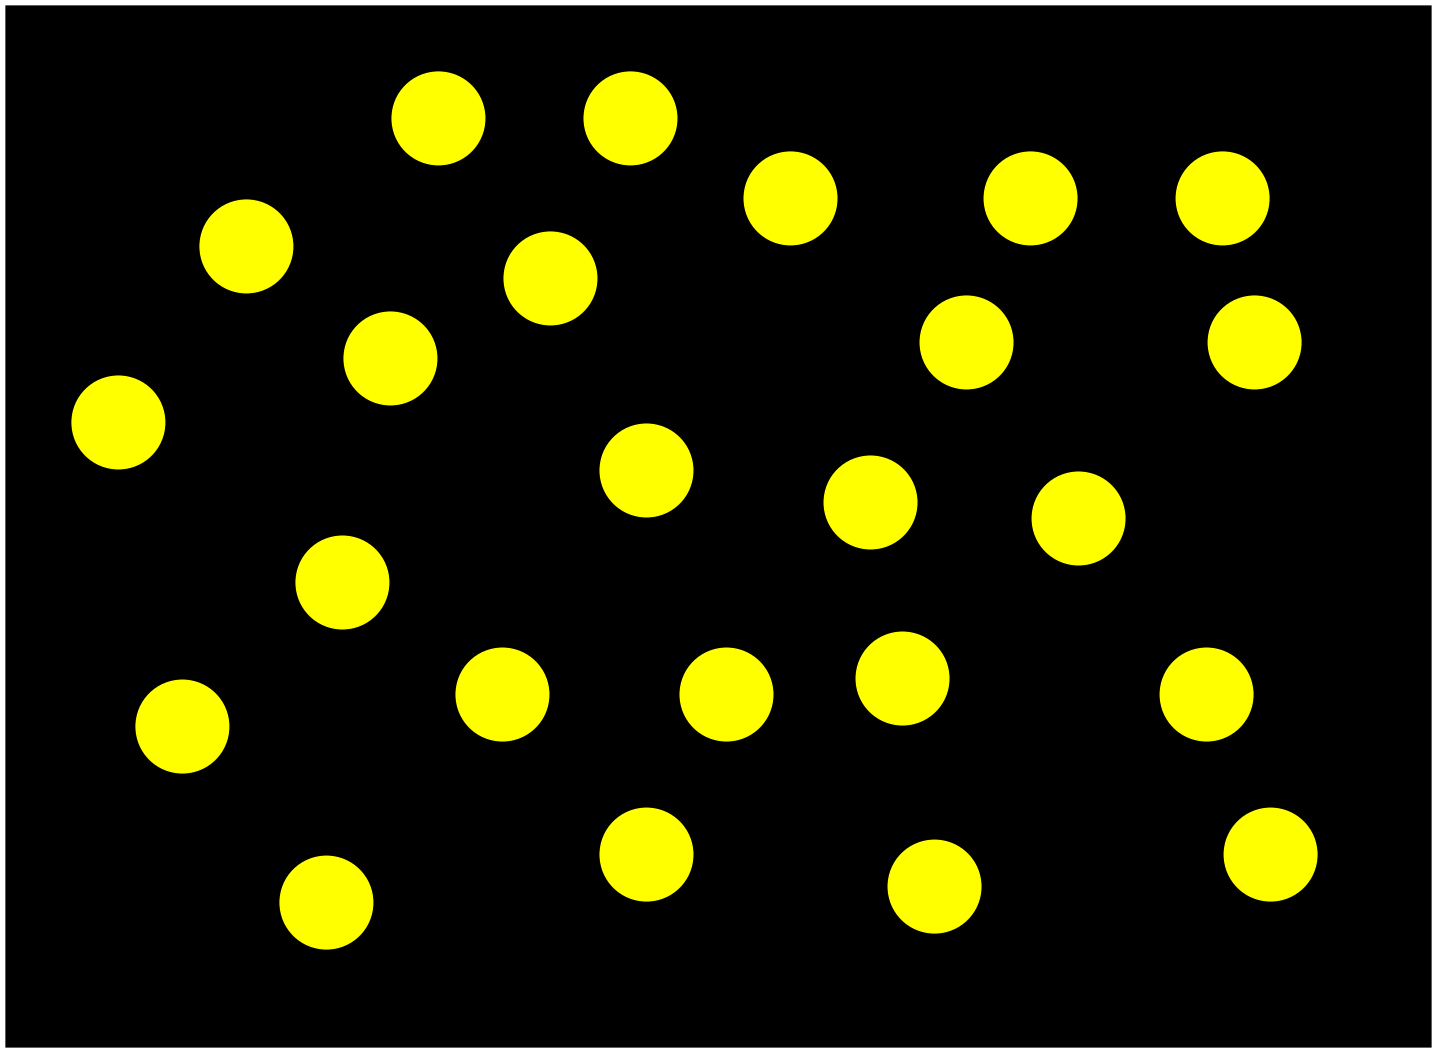
Which has more dots?



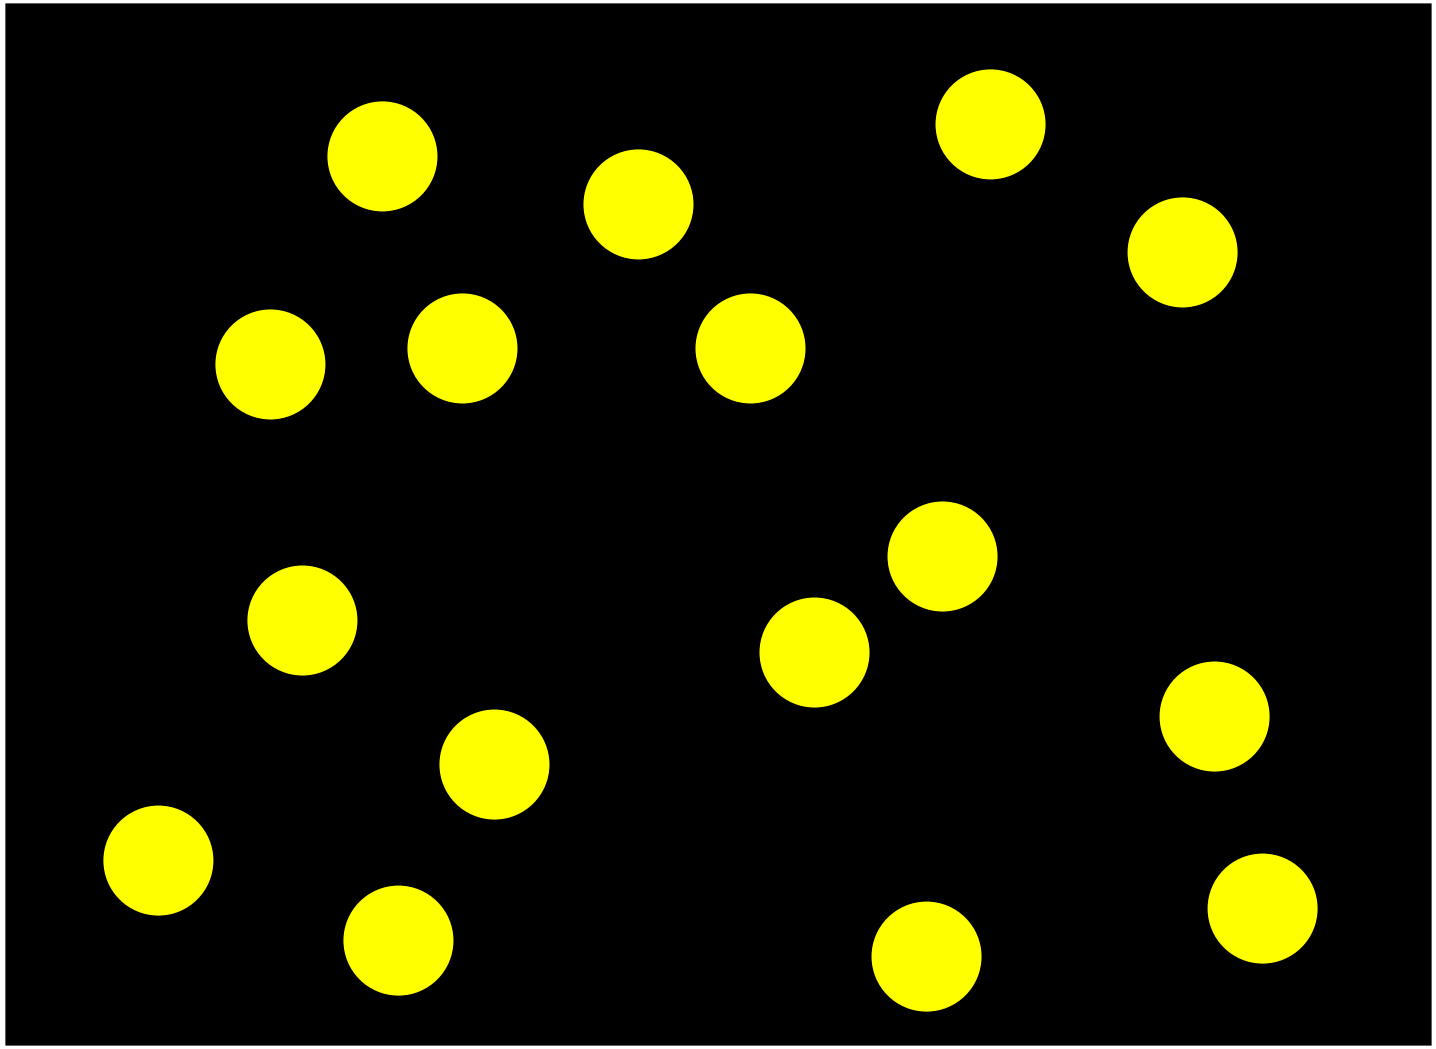


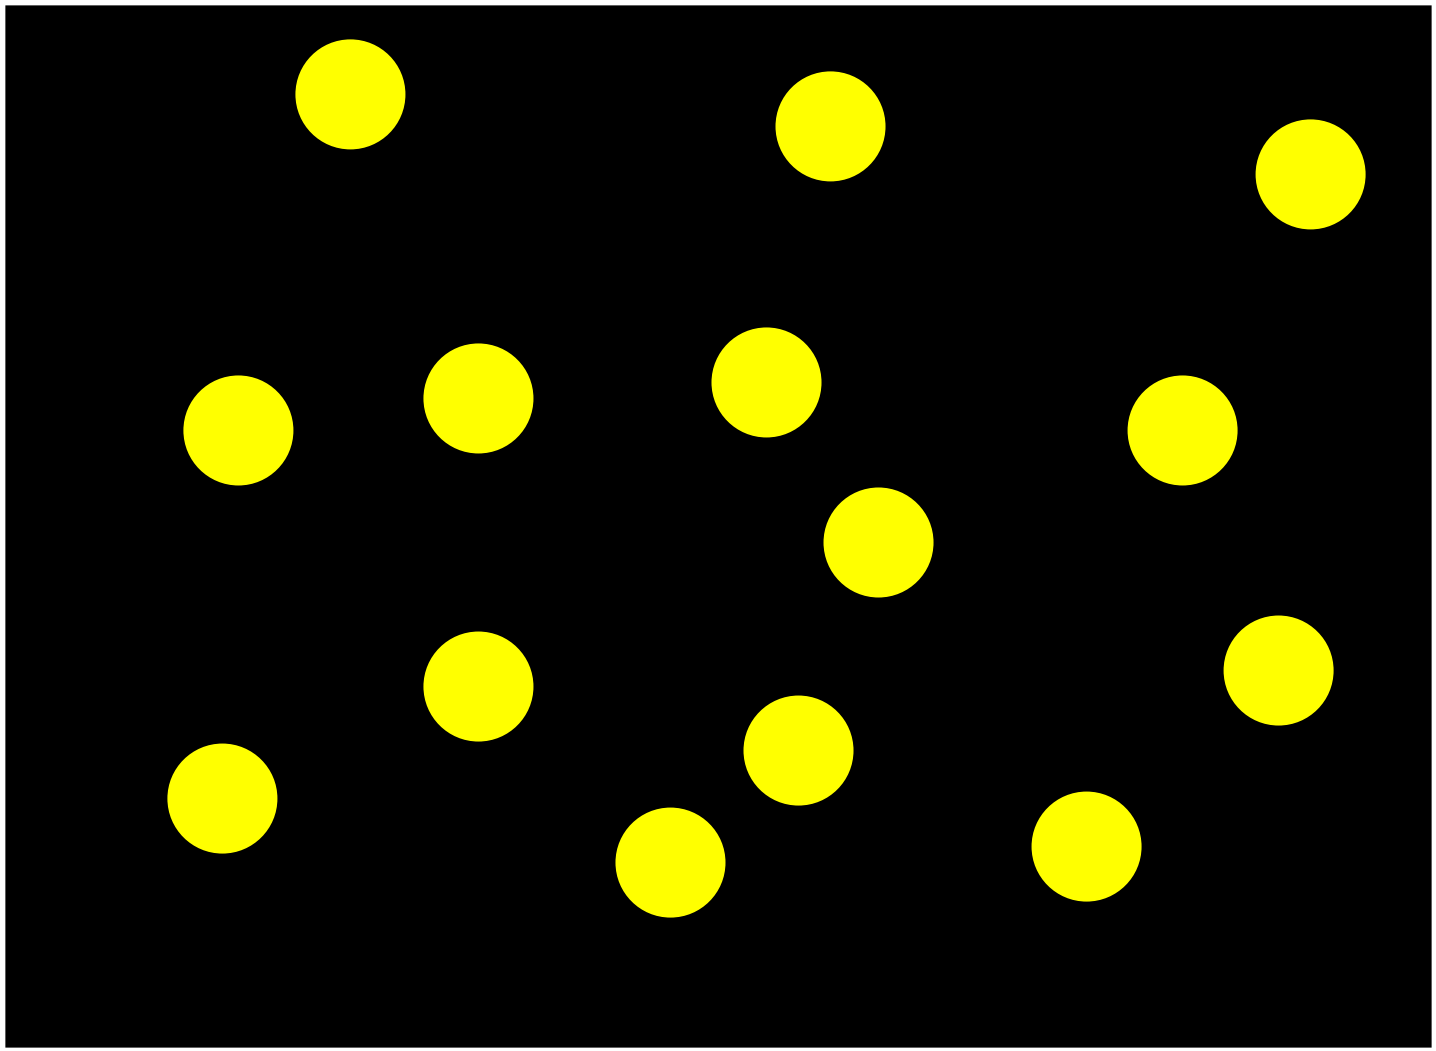
Which has more dots?



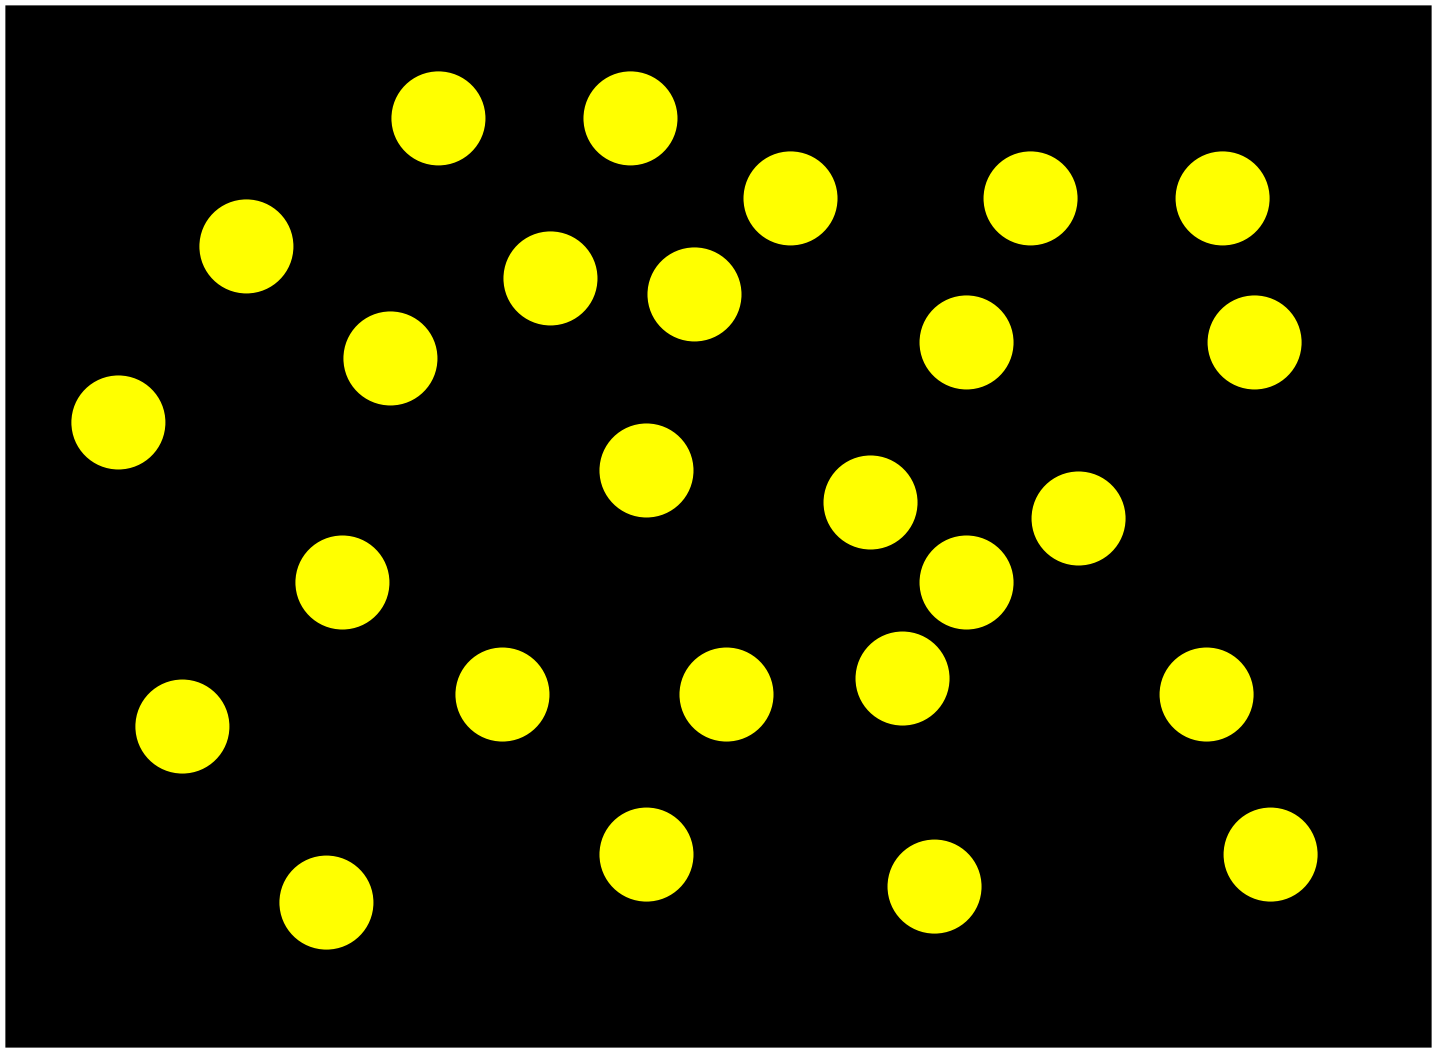


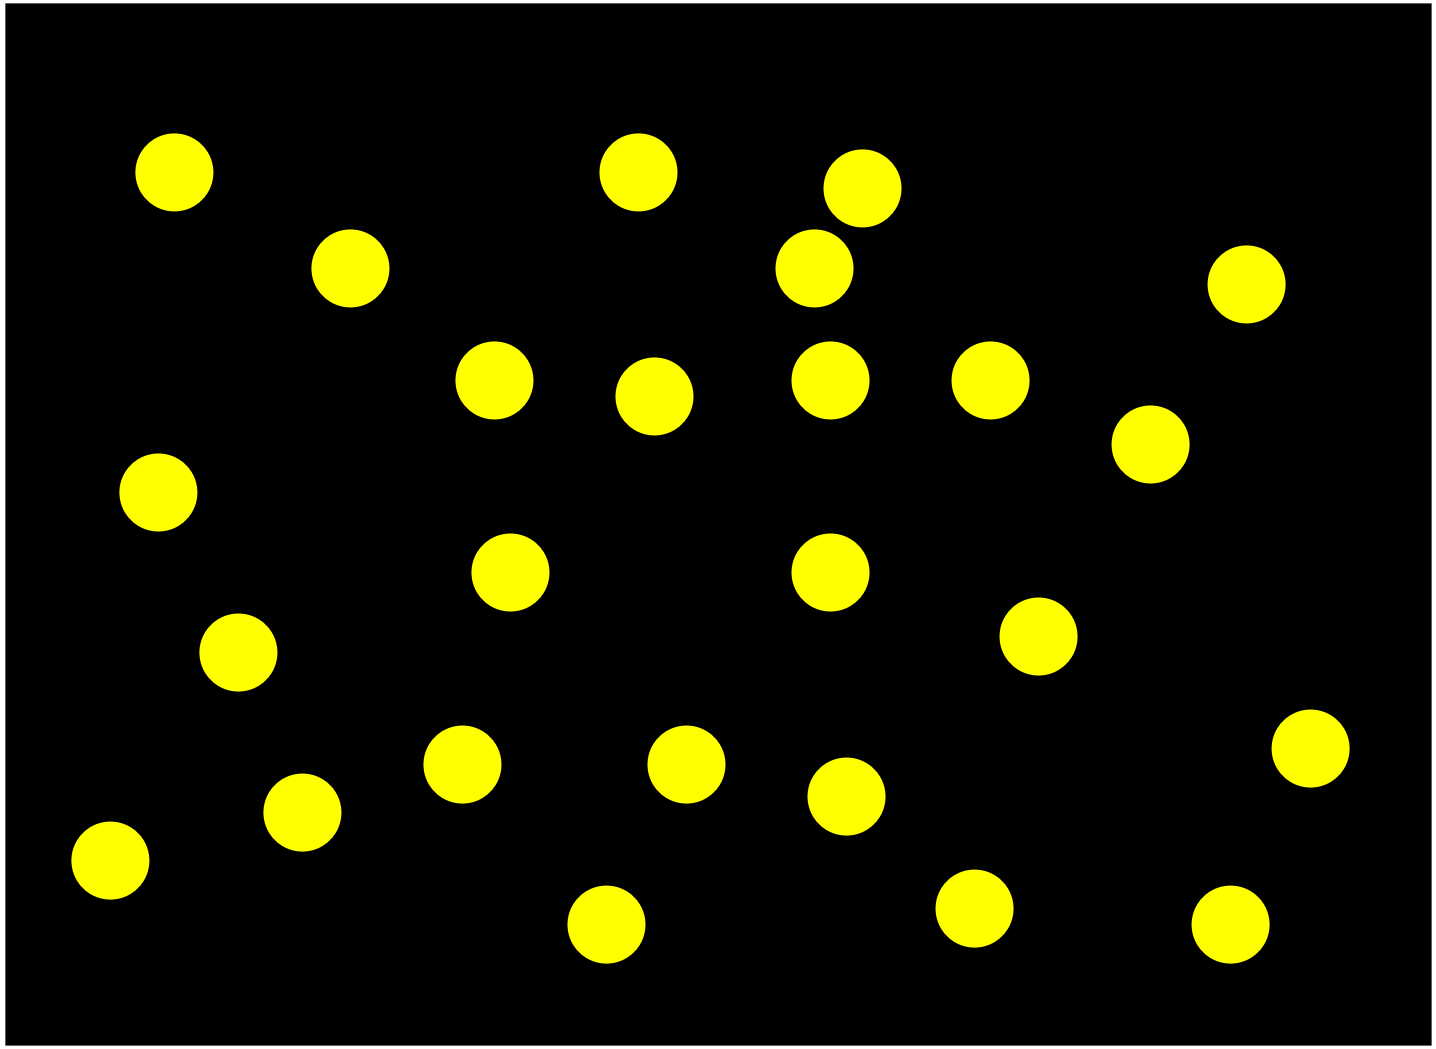
Which has more dots?





Which has more dots?



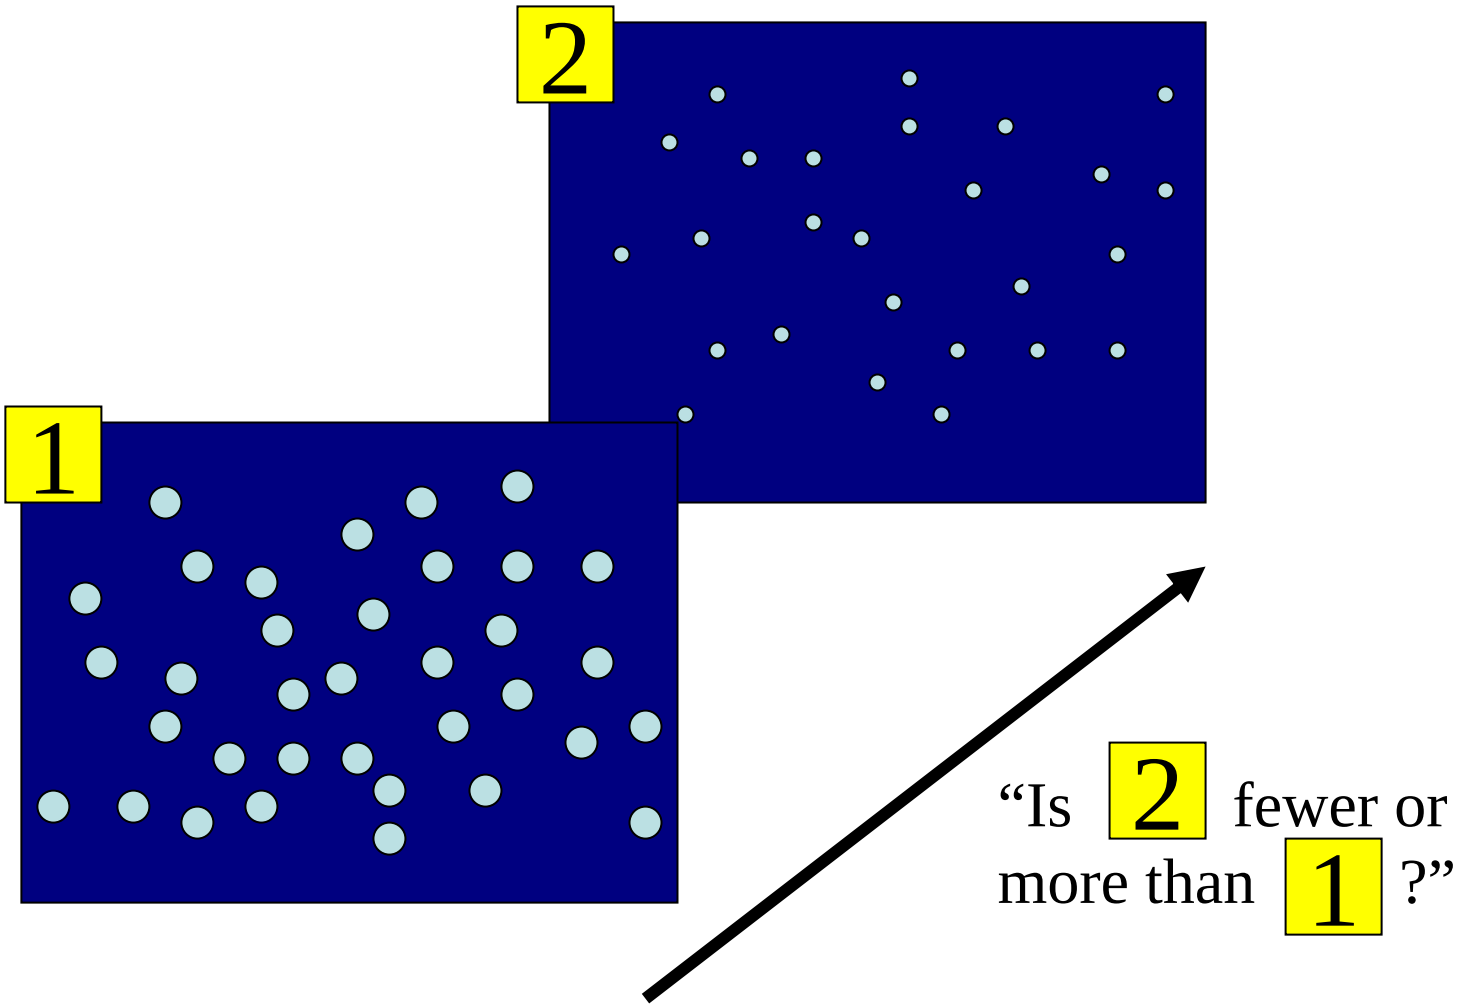


How did you do this?

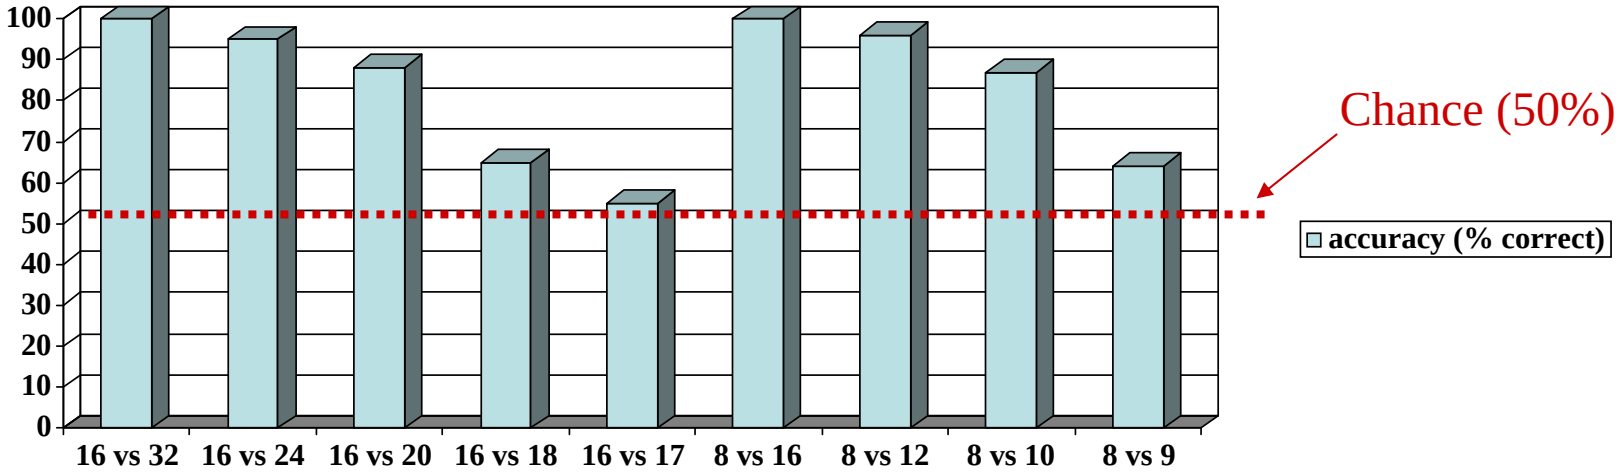
Did you count verbally?

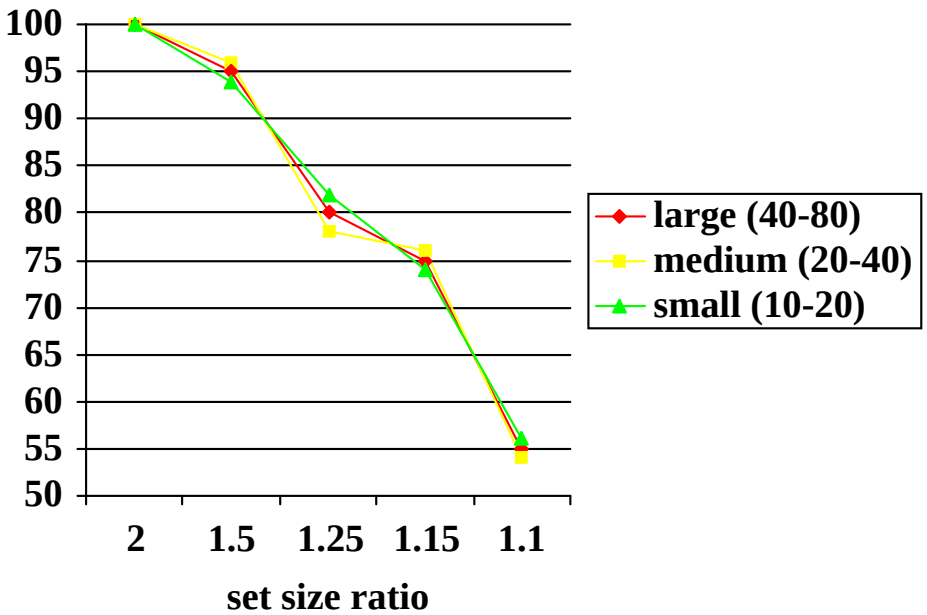
Which ones were harder?

How accurate are adults' large number representations? (Barth, Kanwisher & Spelke, 2003)



Numerosity discrimination by adults (Barth)





Weber's Law:
The discriminability of two numerosities depends on their *ratio* (not absolute diff).

What does “number sense” mean?

✓ • Adults can represent large numerical magnitudes without verbal counting.

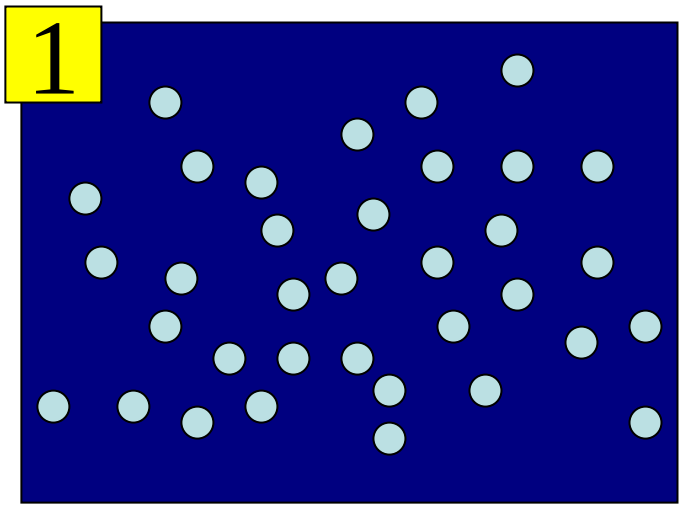
✓ • The representations are approximate; discriminability of two numerosities depends on their ratio.

✓ • The representations are not based on continuous quantities like *area*, but rather on discrete *number*.

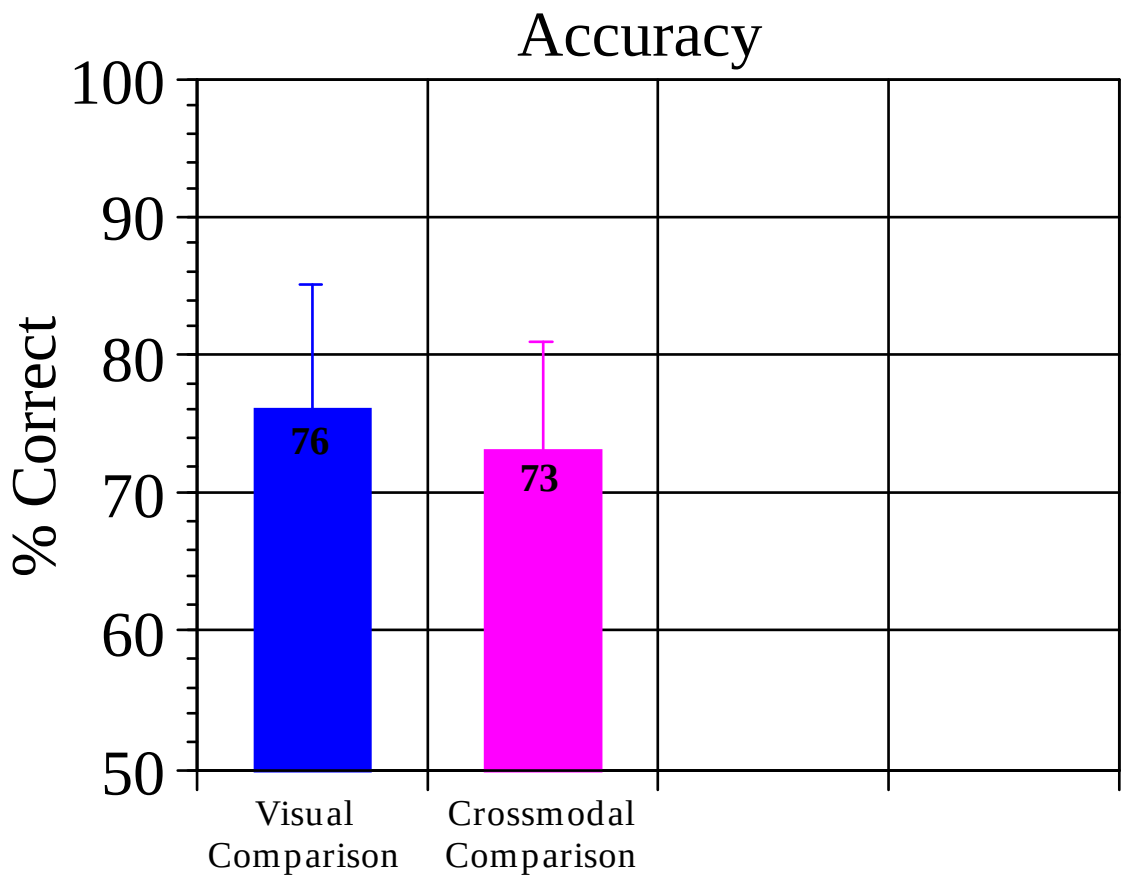
? • The representations are abstract.

? • The representations enter into arithmetic computations (addition).

How abstract are adults' large number representations?



"Is 2 fewer or more than 1 ?"



Cross-modal comparisons are almost as accurate as comparisons within the visual modality alone.

What does “number sense” mean?

✓ • Adults can represent large numerical magnitudes without verbal counting.

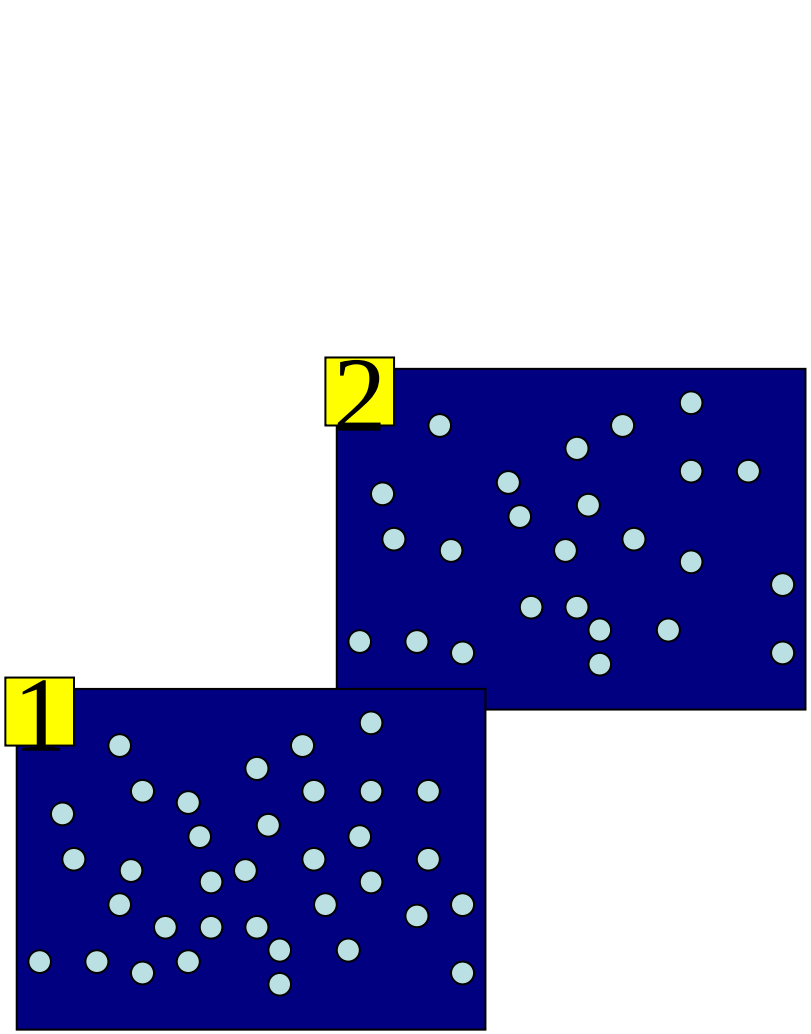
✓ • The representations are approximate; discriminability of two numerosities depends on their ratio.

✓ • The representations are not based on continuous quantities like *area*, but rather on discrete *number*.

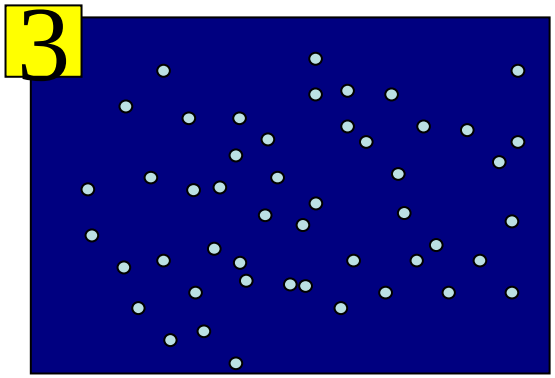
✓ • The representations are abstract.

? • The representations enter into arithmetic computations (addition).

What can adults do with these large number representations?
Addition of visual arrays

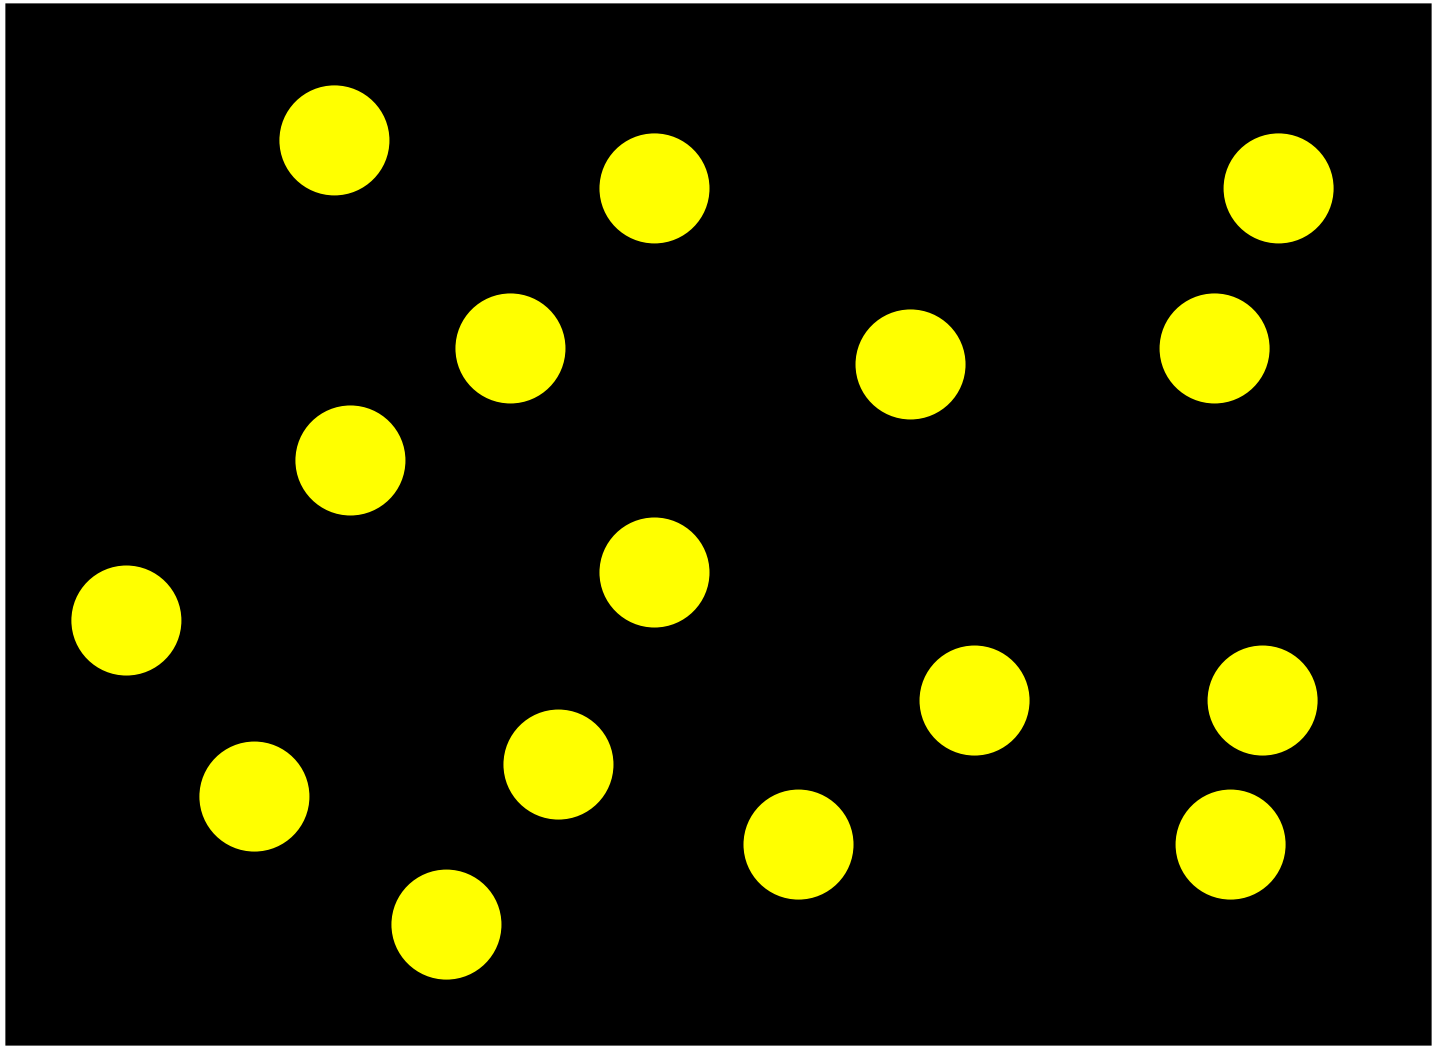


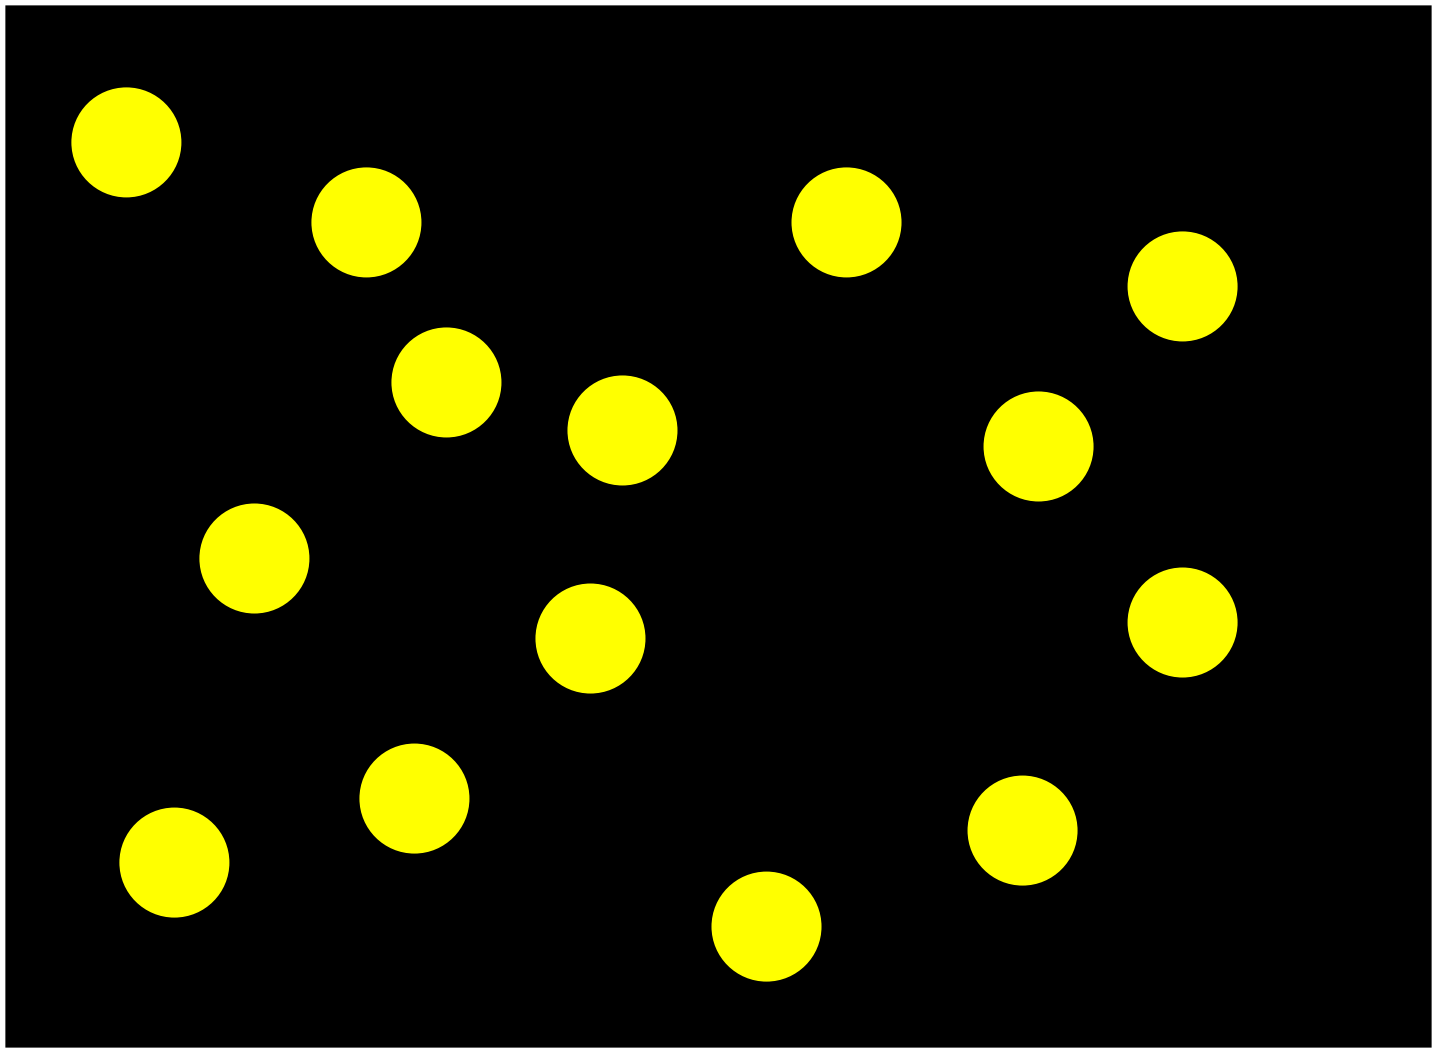
"add"



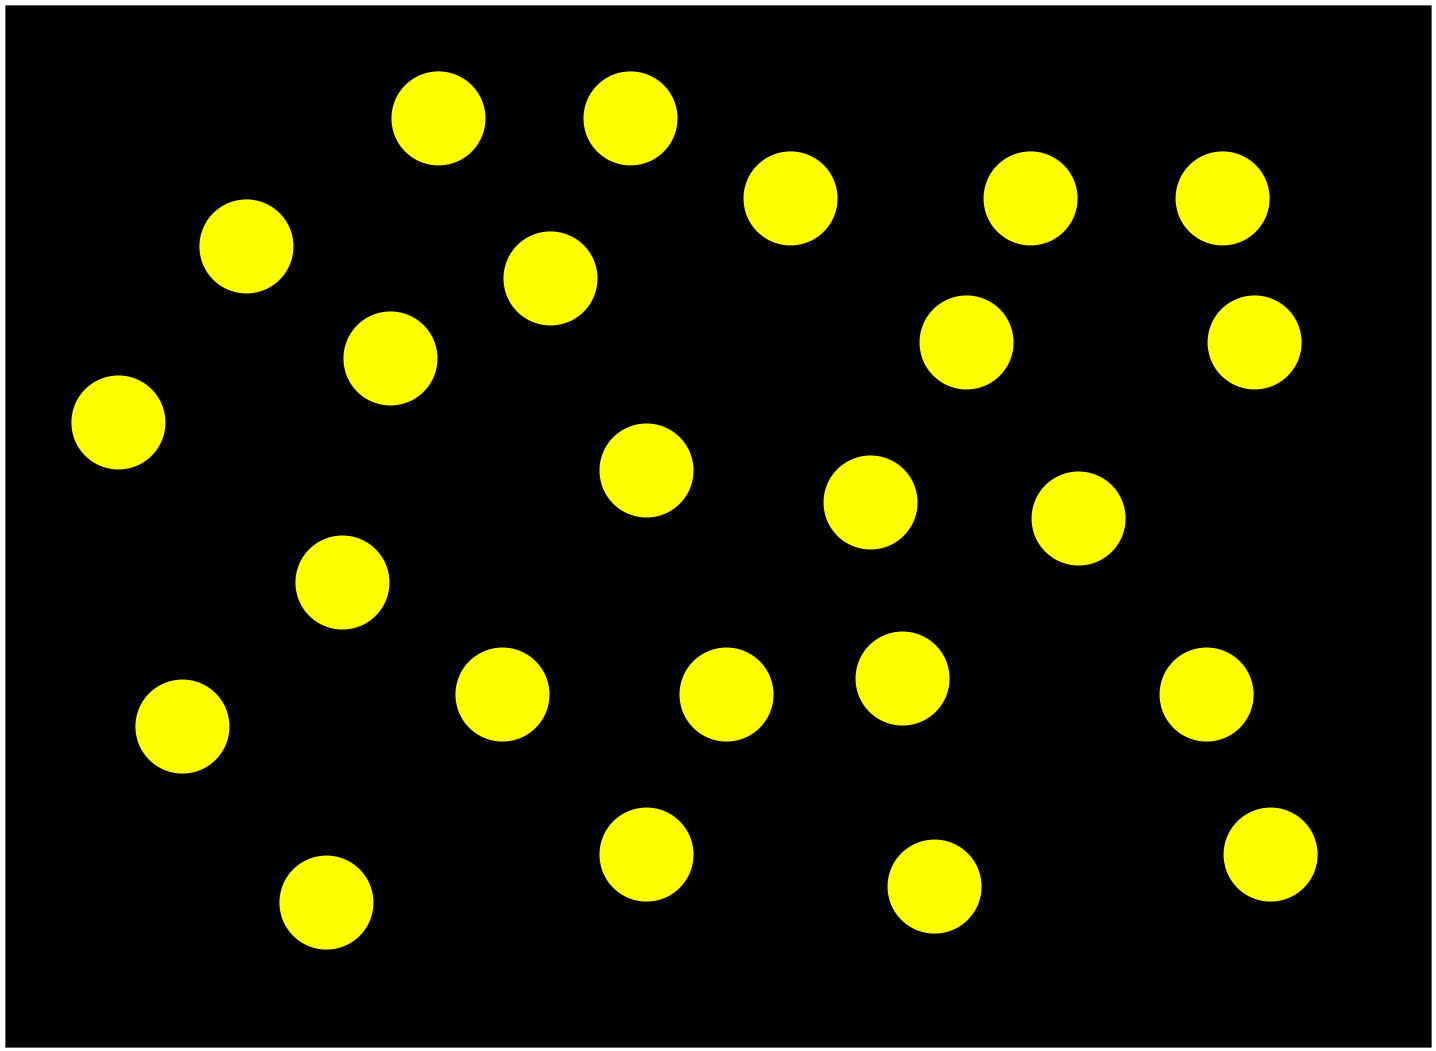
For example…

"Is the sum of 1 and 2 fewer or more than 3 ?"

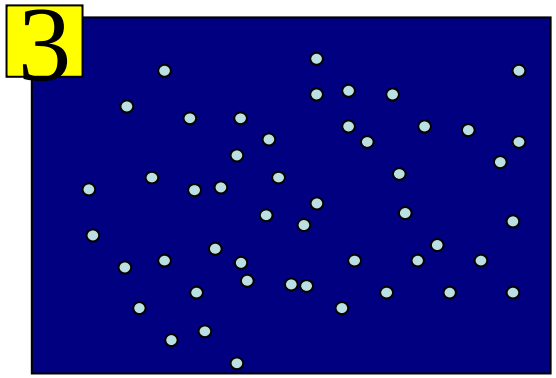




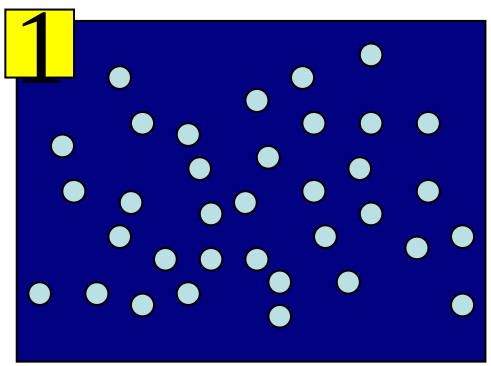
add



What can adults do with these large number representations?
Cross-modal addition

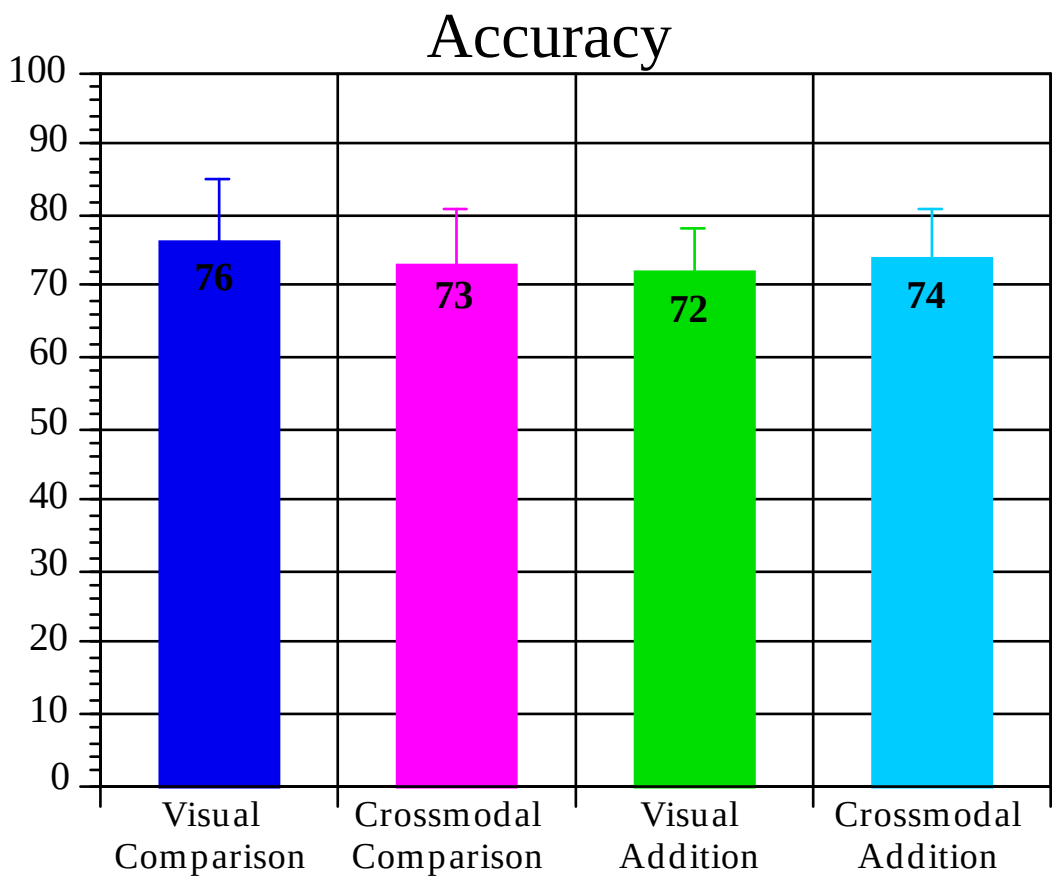


"add"



"Is the sum of 1 and 2 fewer or more than 3 ?"

Nonsymbolic Comparison and Addition



Barth (2001)

What does “number sense” mean?

✓ • Adults can represent large numerical magnitudes without verbal counting.

✓ • The representations are approximate; discriminability of two numerosities depends on their ratio.

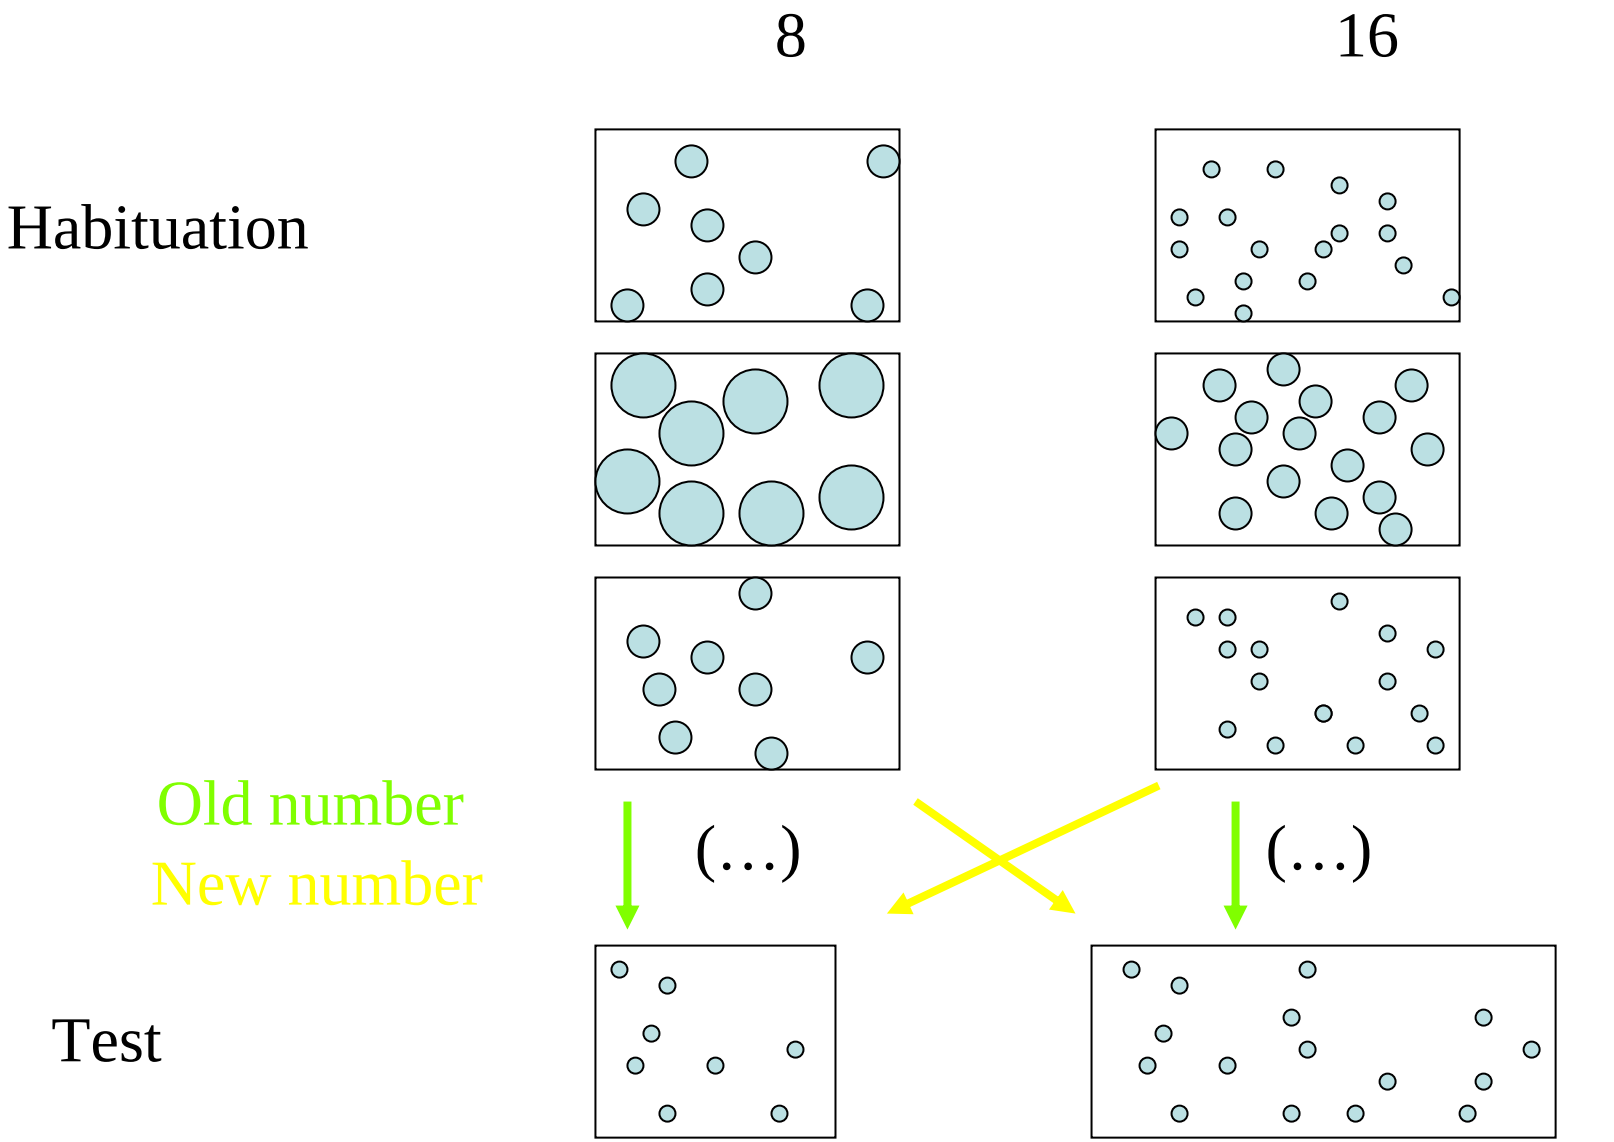
✓ • The representations are not based on continuous quantities like *area*, but rather on discrete *number*.

✓ • The representations are abstract.

✓ • The representations enter into arithmetic computations (addition).

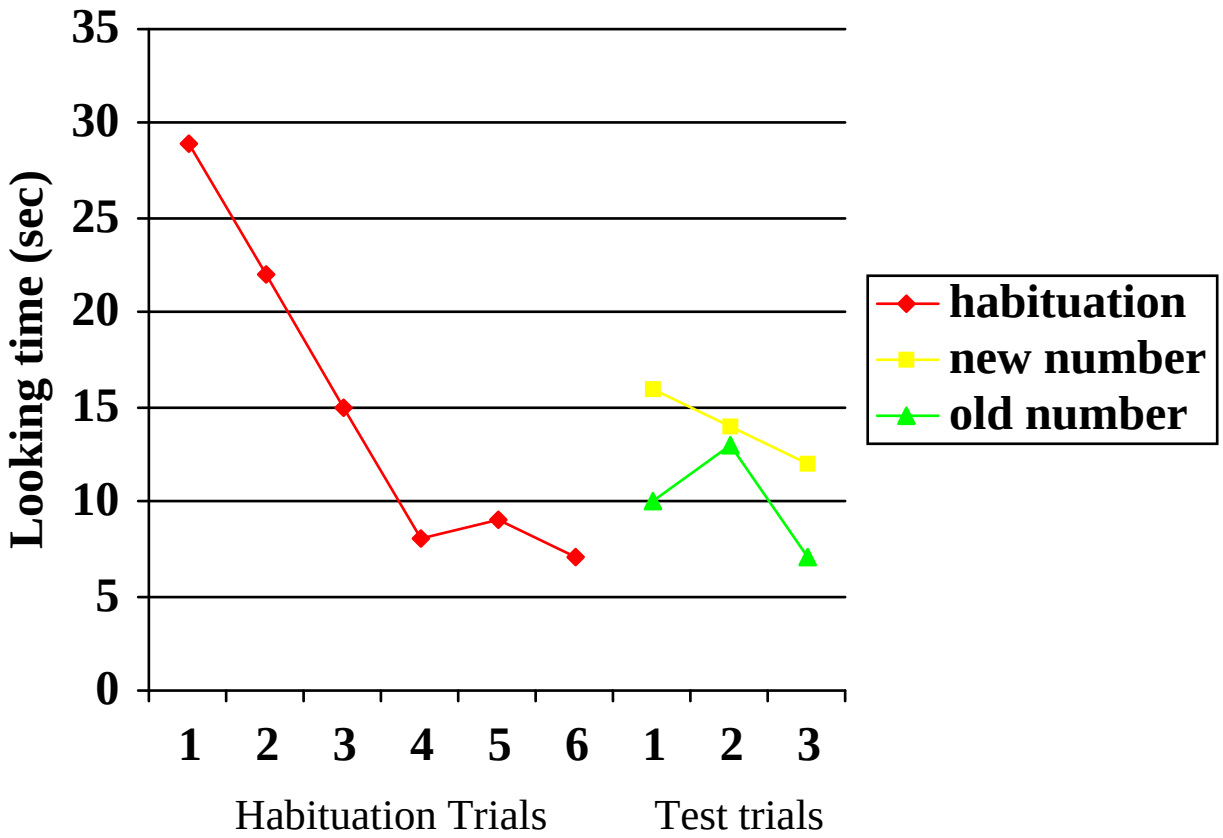
But: the people in these studies have spent years learning and using formal arithmetic. Do these abilities exist in infants? Animals?

Large number representations in infants



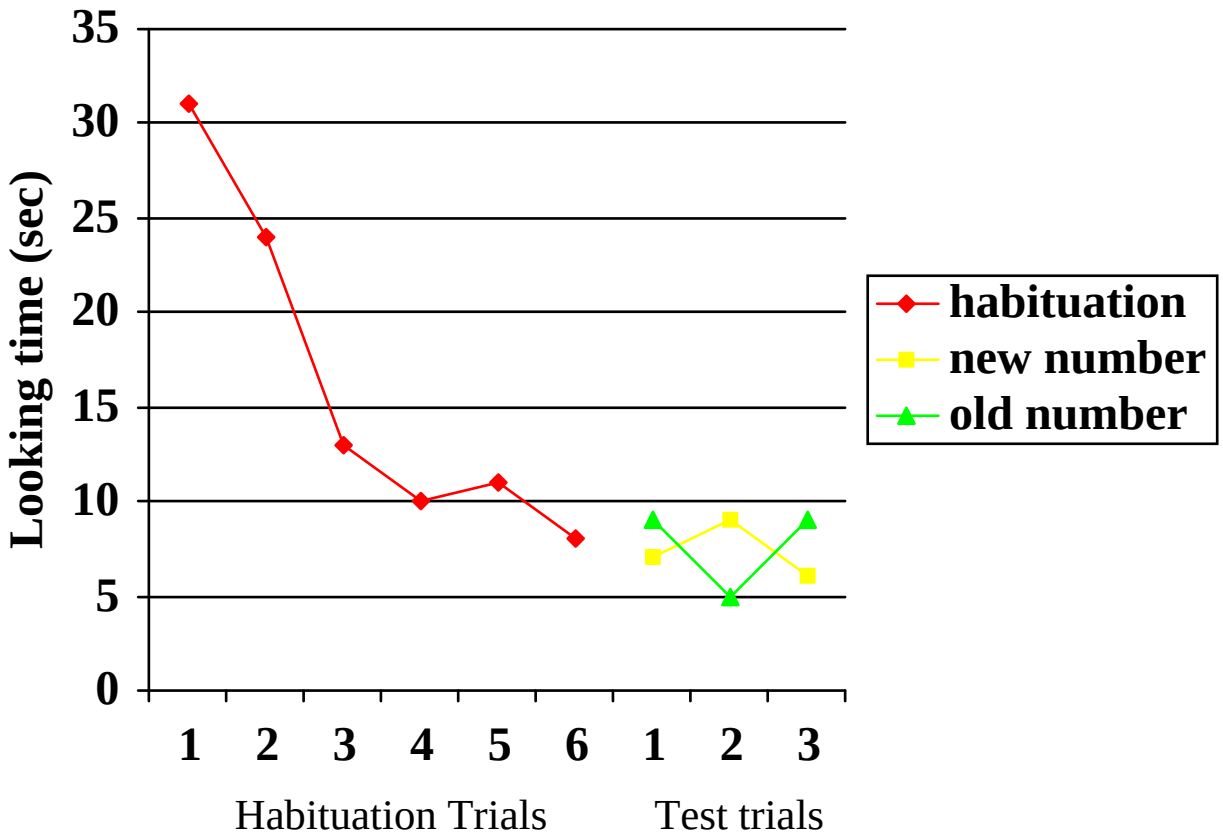
Xu & Spelke (2000)

Discriminating 8 vs. 16 dots at 6 months



Infants discriminate between large numerosities in dot arrays.

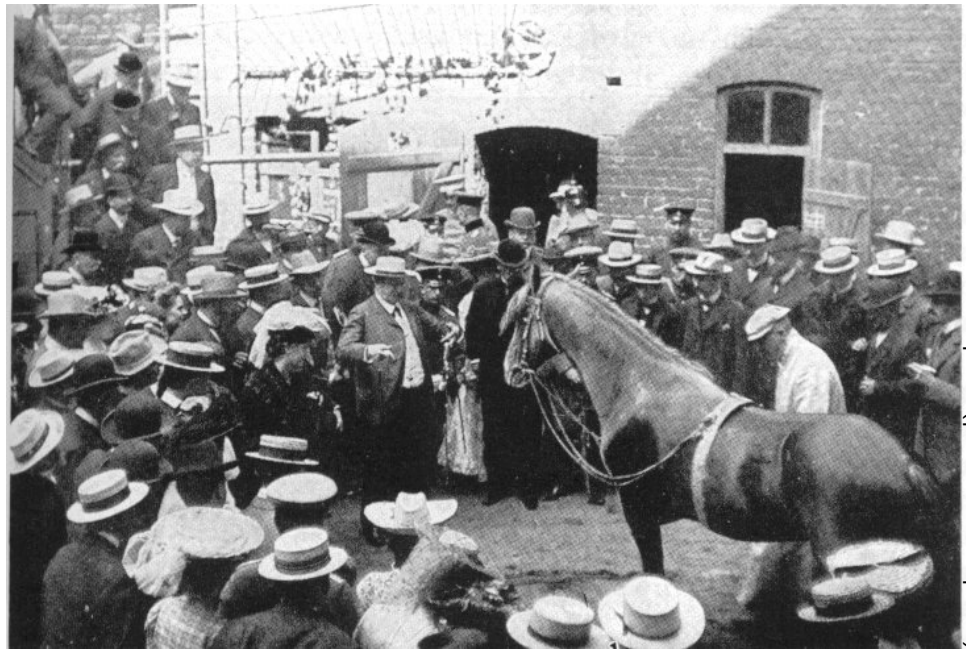
Discriminating 8 vs. 12 dots at 6 months



Infants' number representations are imprecise.

Large number representations in non-human animals

The case of Clever Hans

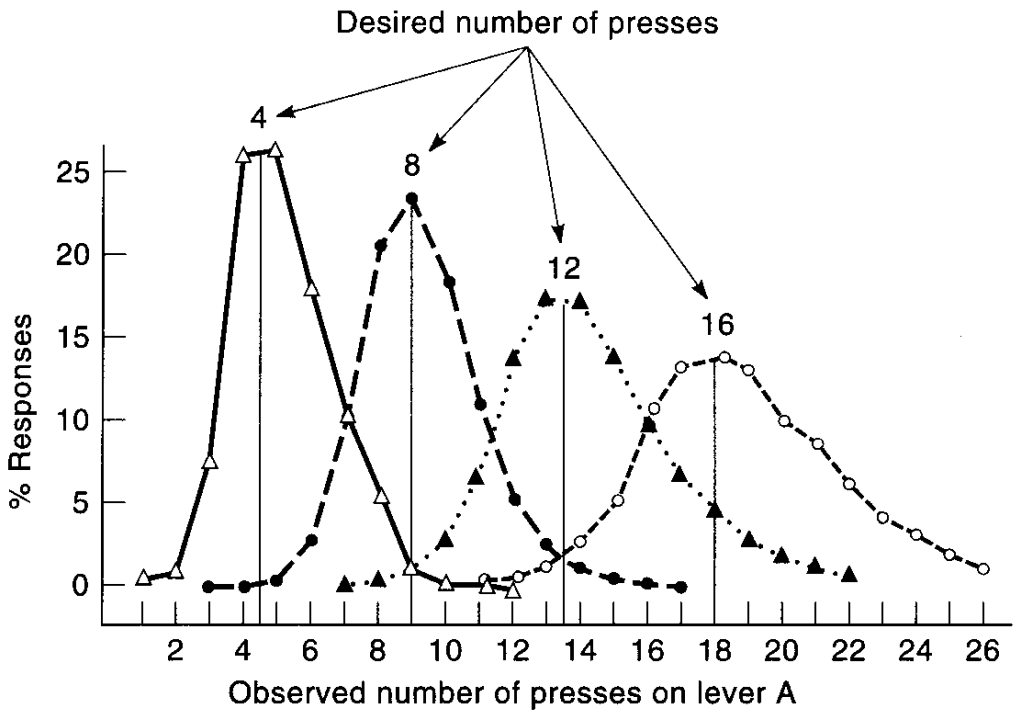


Source: Wikipedia (public domain photo).

Arguments against number representations in animals: what good is number?

- foraging? (continuous amount, not number)
- keeping track of offspring? (individual recognition, not number)

Large number representations in non-human animals: Evidence from rats (Mechner expts.)



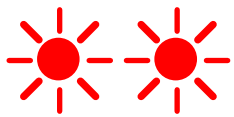
Rats represent the approximate number of presses.
Their representation of number accords with Weber's Law.

Mechner, F. "Probability relations within response sequences under ratio reinforcement." *Journal of the Experimental Analysis of Behavior* 16 (1958): 109-121.

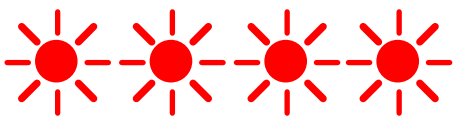
Church & Meck: abstract number in rats

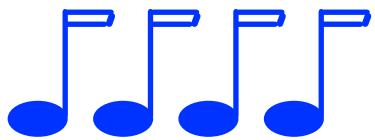
Training phase:

If 2 lights or 2 sounds press "2" lever



If 4 lights or 4 sounds press "4" lever

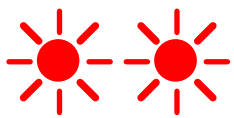


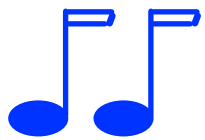


Church & Meck: abstract number in rats

Testing phase:

Present 2 lights AND 2 sounds





Rats press the "4" lever: spontaneous abstraction across modalities!

What does “number sense” mean?

✓ • Adults can represent large numerical magnitudes without verbal counting.

✓ • The representations are approximate; discriminability of two numerosities depends on their ratio.

✓ • The representations are not based on continuous quantities like *area*, but rather on discrete *number*.

✓ • The representations are abstract.

✓ • The representations enter into arithmetic computations (addition).

But: the people in these studies have spent years learning and using formal arithmetic. Do these abilities exist in infants? Animals? *YES!*

They are part of our basic cognitive machinery.

I. Understanding approximate number

- Adults
- Infants
- Animals

II. Brain basis of number:

- neuropsychological patients
- fMRI: understanding approximate number

HUMAN PARIETAL CORTEX

Neuroanatomy

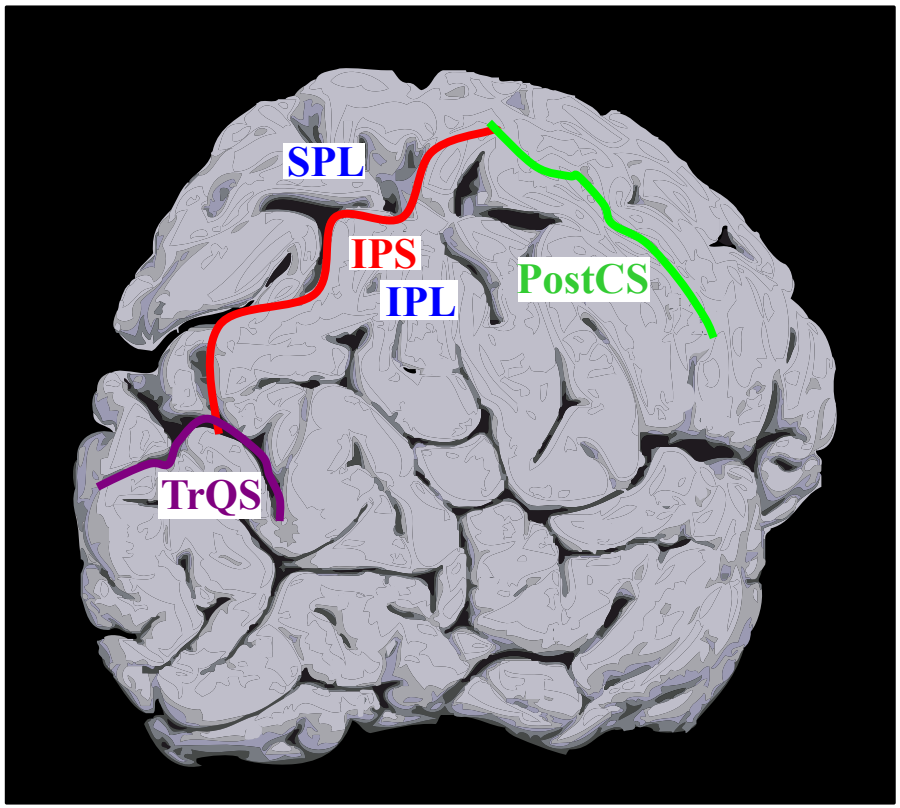


Figure by MIT OpenCourseWare.

Intraparietal sulcus (IPS)
divides superior (SPL) and inferior (IPL) parietal lobules

Neuropsychological Studies

- Lemer, Dehaene, Spelke, Cohen (2003):
  - One “acalculic” patient :
    - Left parietal lobe damage
    - Bad at approximation
    - More impaired on subtraction than multiplication
  - Another “acalculic” patient :
    - left temporal
    - Intact approximation
    - More imparied at multiplication than subtraction

•Taken together, these two patients are a……..???

fMRI: Comparing “Approximate Vs. Exact” calculation (Dehaene et al, 1999)

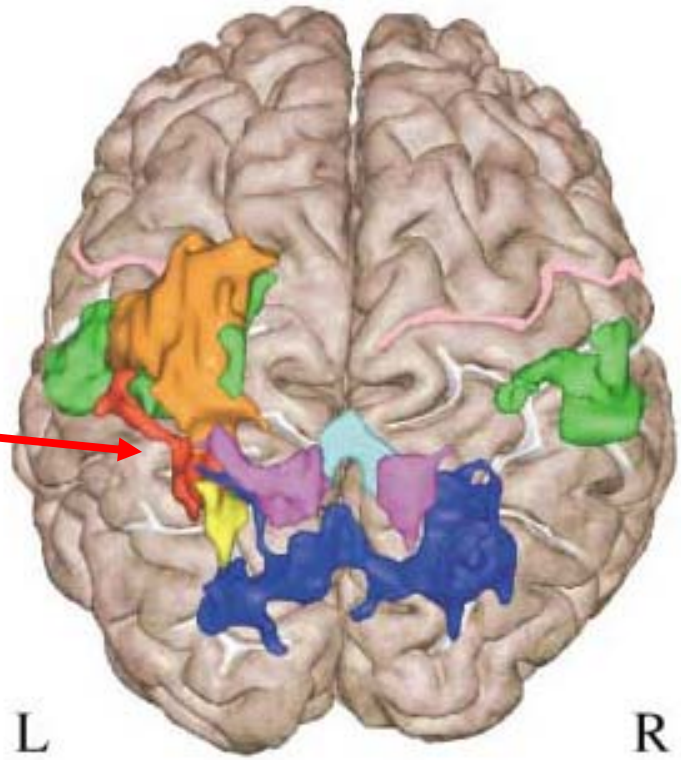
Dehaene-Spelke Results

- Approximate > exact activations (in yellow) in the intaparietal sulci, extending anteriorily to the depth of the postcentral sulcus and laterally into the inferior parietal lobule

Simon, Mangin, Cohen, Le Bihan & Dehaene, *Neuron*, 2002

"HIPS"



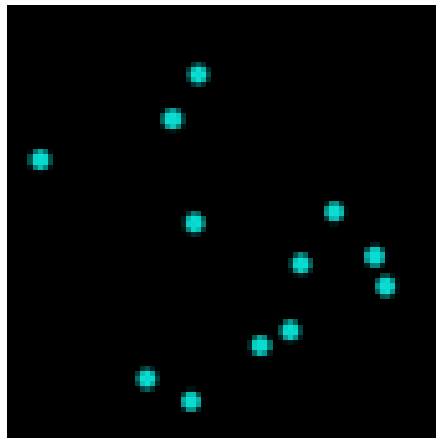
Claim: this parietal region is the approximate number system that has been characterized behaviorally.

But only tested with symbolic number.

Grasping only
Saccades only
Calculation only
Attention only
Manual tasks
Visuo-spatial tasks
Calculation, Saccades and Language

Shuman & Kanwisher (2004)

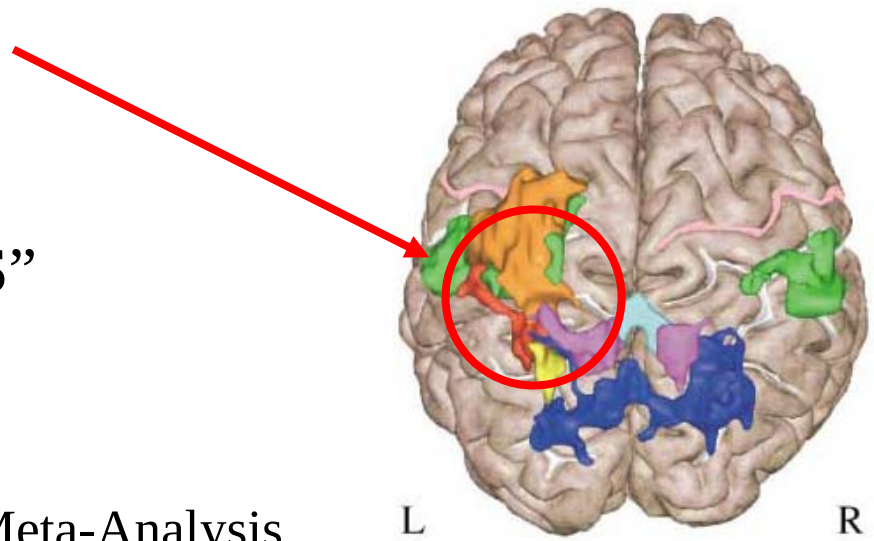
- Are these parietal regions engaged in processing abstract numerical magnitude?
  - Test using *non-symbolic* number:



- Are these parietal regions *selectively* engaged in processing numerical magnitude?

Design

- fMRI using 2 methods:
  - Task Manipulation
  - Adaptation
- ROI method: Look in “HIPS”

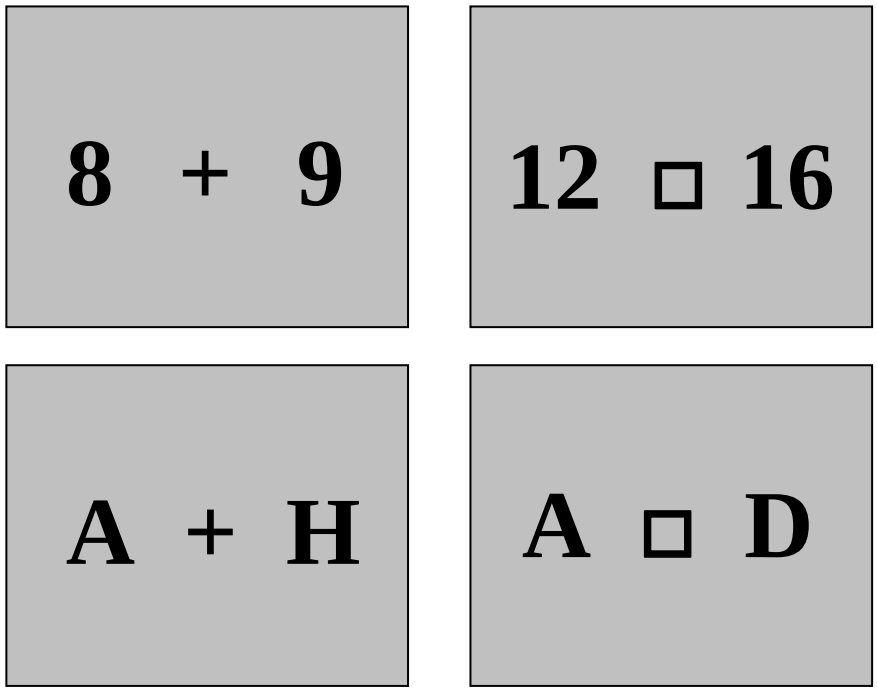


–Mean Coordinates from Meta-Analysis

–Individual, Functionally Defined ROIs

using Dehaene’s letter approximation task as a localizer

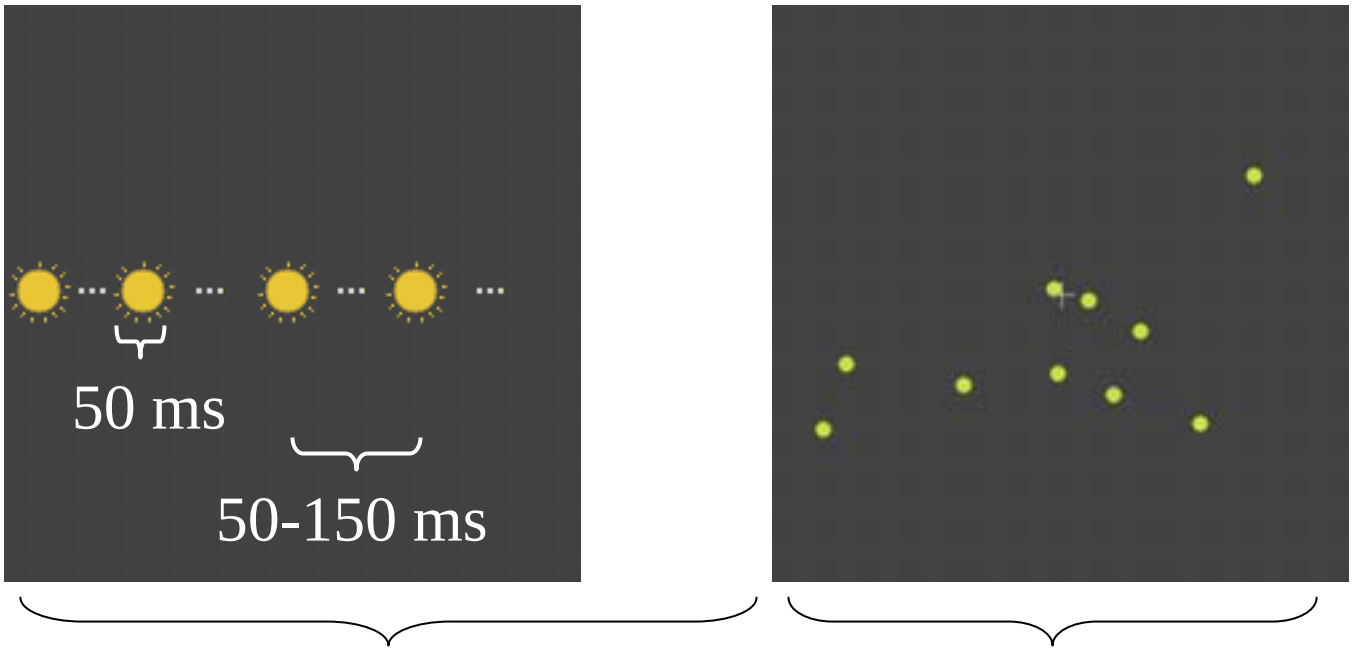
Localizer task: Dehaene et al, 1999, *Science*



Approximate Addition

Letter Comparison

Experiment 1: Task Manipulation

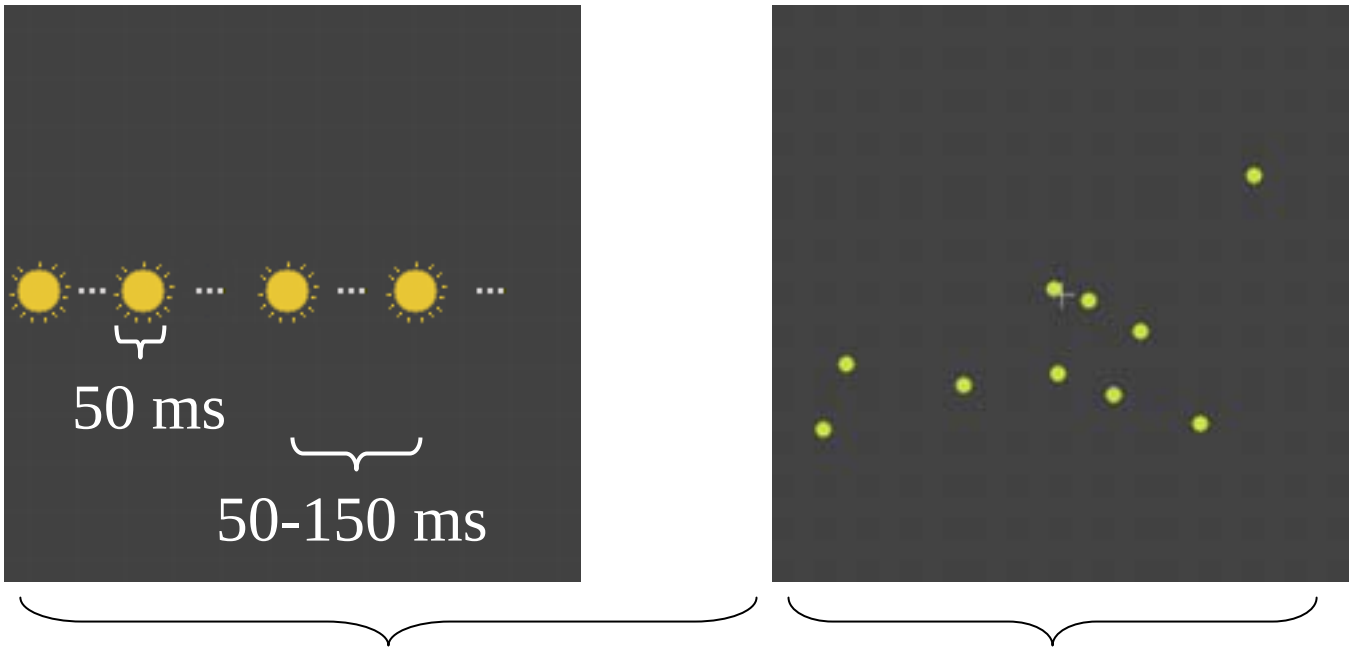


Number:
More Flashes or Dots?

OR

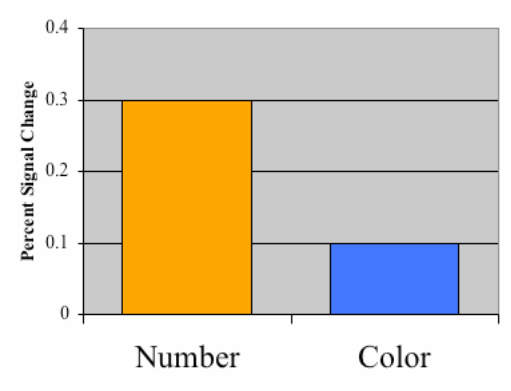
Color:
Same or different?

Experiment 1: Task Manipulation

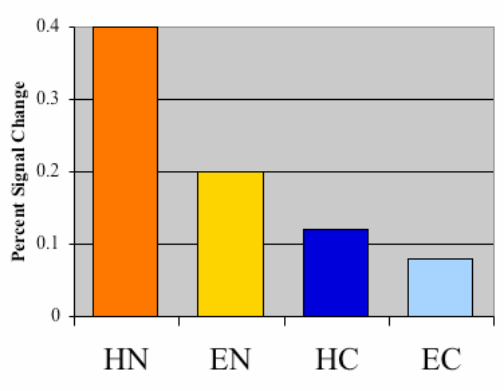


2 x 2 Design:
Difficulty (Hard / Easy) x Task (Number / Color)

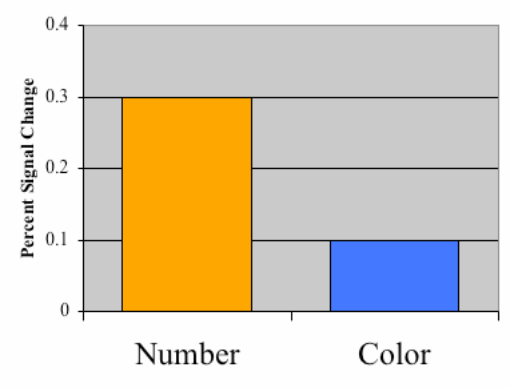
Predictions for a “number” region:

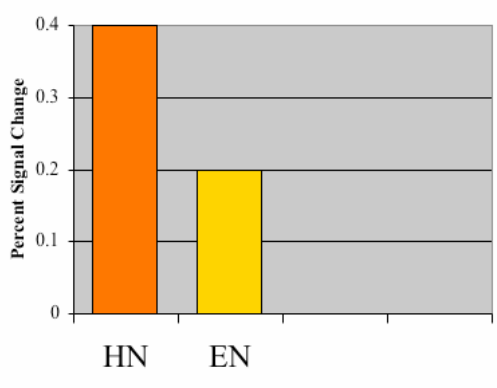


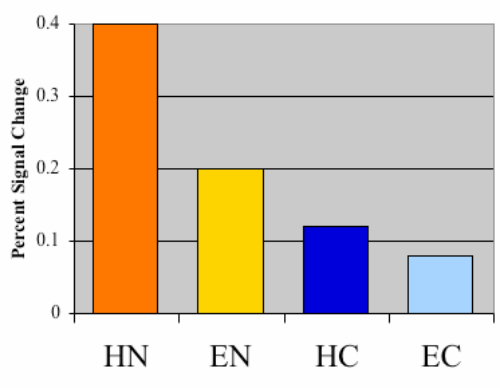
and



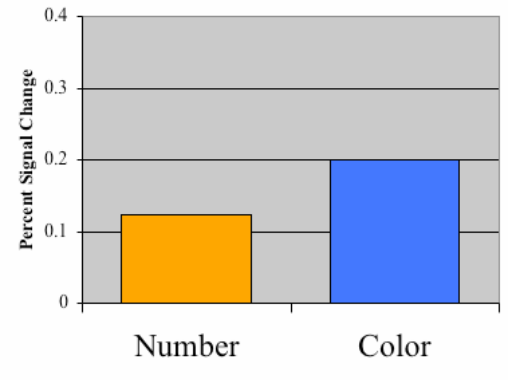
Predictions for a “number” region: :

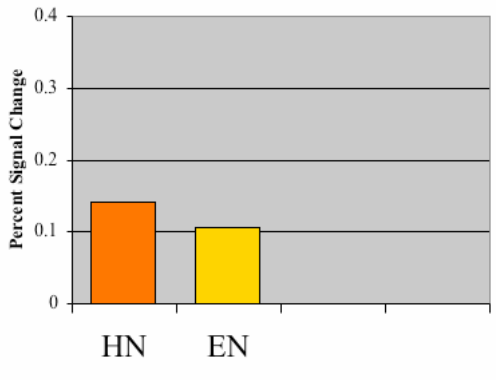


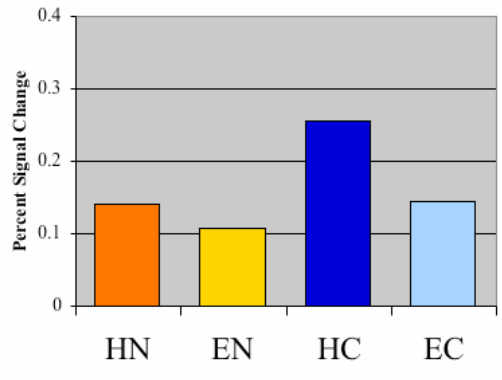




Results in HIPS:



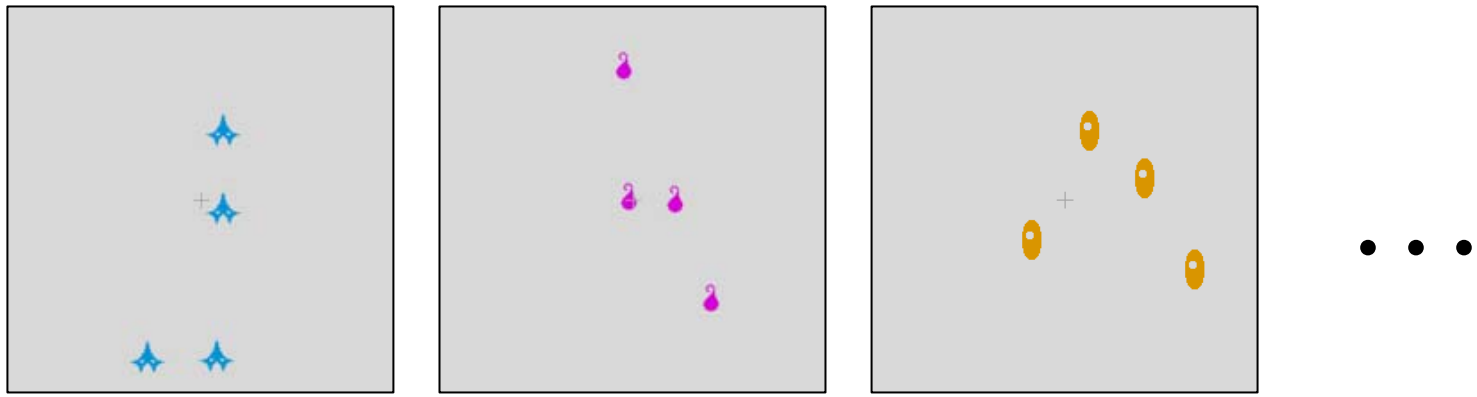




Doesn’t look like a number region.

Experiment 2: fMRI Adaptation

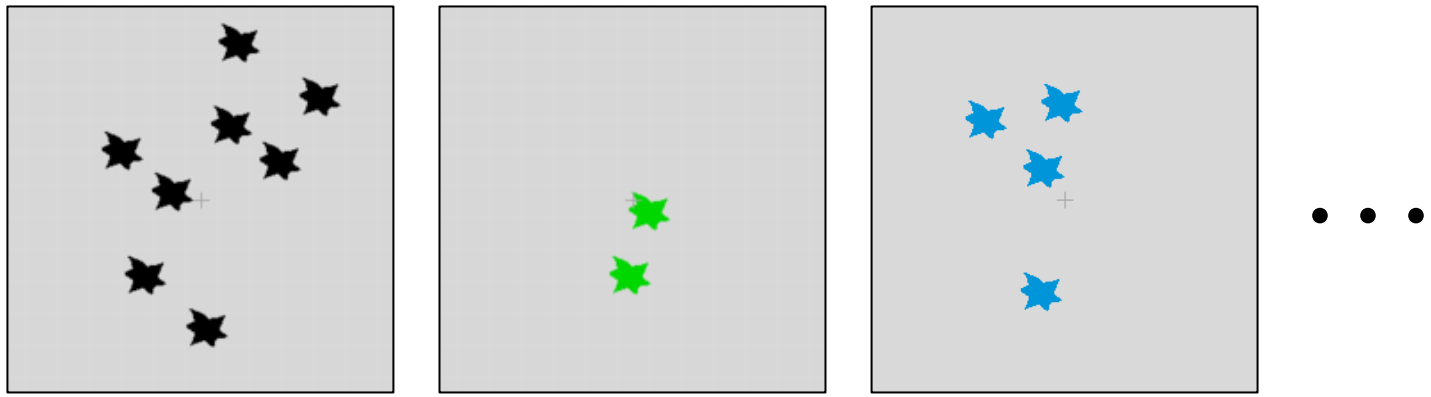
Experiment 2: fMRI Adaptation



Sequence of 16 different shape arrays
Blocked; task = Passive viewing or color ‘1-back’

	Shape Const	Shape Varies
Number Const		
Numb. Varies		

Experiment 2: fMRI Adaptation



Sequence of 16 different shape arrays

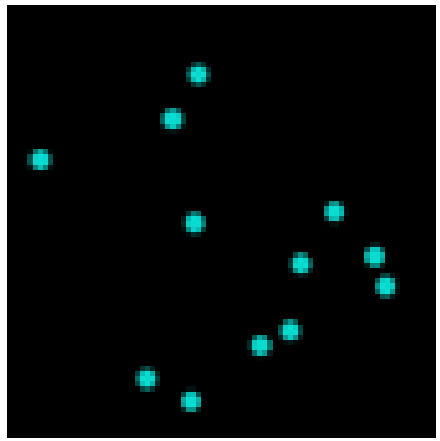
Shuman & Kanwisher (2004)

- Are these parietal regions engaged in processing abstract numerical magnitude?
  - Test using *non-symbolic* number:



- Are these parietal regions *selectively* engaged in processing numerical magnitude?

No evidence in our data for parietal regions selectively engaged in processing number. But this debate goes on…..

Understanding Number: What is the evidence for these Claims?

- "animals, young infants, and adult humans possess a biologically determined, domain-specific representation of number"

- "a specific neural substrate, located in the left and right intraparietal area, is associated with knowledge of numbers and their relations ('number sense'). The number domain is a prime example where strong evidence points to an evolutionary endowment of abstract domain-specific knowledge in the brain because there are parallels between number processing in animals and humans."

–Dehaene, Dehaene-Lambertz & Cohen, TINS, 1998
