6.003: Signals and Systems

CT Feedback and Control

October 20, 2011

Mid-term Examination #2

Wednesday, October 26, 7:30-9:30pm,

No recitations on the day of the exam.

Coverage: Lectures 1–12 Recitations 1–12 Homeworks 1–7

Homework 7 will not be collected or graded. Solutions will be posted.

Closed book: 2 pages of notes $(8\frac{1}{2} \times 11 \text{ inches}; \text{ front and back}).$

No calculators, computers, cell phones, music players, or other aids.

Designed as 1-hour exam; two hours to complete.

Review sessions during open office hours.

Conflict? Contact before Friday, Oct. 21, 5pm.

Feedback and Control

Feedback: simple, elegant, and robust framework for control.

Last time: robotic driving.

Feedback and Control

Using feedback to enhance performance.

Examples:

- increasing speed and bandwidth
- controlling position instead of speed
- reducing sensitivity to parameter variation
- reducing distortion
- stabilizing unstable systems
 - magnetic levitation
 - inverted pendulum

Op-amps

An "ideal" op-amp has many desireable characteristics.

$$V_{+} \circ + K$$

 $V_{-} \circ - V_{o} = K (V_{+} - V_{-})$

- high speed
- large bandwidth
- high input impedance
- low output impedance
- ...

It is difficult to build a circuit with all of these features.

The gain of an op-amp depends on frequency.

Frequency dependence of LM741 op-amp.

Low-gain at high frequencies limits applications.

Unacceptable frequency response for an audio amplifier.

An ideal op-amp has fast time response.

Determine the step response of an LM741.

System function: $K(s) = \frac{\alpha K_0}{s + \alpha}$

Impulse response:

$$h(t) = \alpha K_0 e^{-\alpha t} u(t)$$

Step response:

$$s(t) = \int_{-\infty}^{t} h(\tau) d\tau = \int_{0}^{t} \alpha K_{0} e^{-\alpha \tau} d\tau = \left. \frac{\alpha K_{0} e^{-\alpha \tau}}{-\alpha} \right|_{0}^{t} = K_{0} (1 - e^{-\alpha t}) u(t)$$

Parameters:

$$A = K_0 = 2 \times 10^5$$

$$\tau = \frac{1}{\alpha} = \frac{1}{40} \,\mathrm{s}$$

Performance parameters for real op-amps fall short of the ideal.

Frequency Response: high gain but only at low frequencies.

Step Response: slow by electronic standards.

We can use feedback to improve performance of op-amps.

circuit

6.003 model

$$V_{-} = \beta V_o = \left(\frac{R_2}{R_1 + R_2}\right) V_o$$

Dominant Pole

Op-amps are designed to have a dominant pole at low frequencies: \rightarrow simplifies the application of feedback.

Using feedback to improve performance parameters.

Using feedback to improve performance parameters.

What is the most negative value of the closed-loop pole that can be achieved with feedback?

Open loop system function: $\frac{\alpha K_0}{s+\alpha}$ \rightarrow pole: $s = -\alpha$.

Closed-loop system function: $\frac{\alpha K_0}{s + \alpha + \alpha \beta K_0}$

 \rightarrow pole: $s = -\alpha(1 + \beta K_0)$.

The feedback constant is $0 \le \beta \le 1$.

 \rightarrow most negative value of the closed-loop pole is $s = -\alpha(1 + K_0)$.

Feedback extends frequency response by a factor of $1 + \beta K_0$ ($K_0 = 2 \times 10^5$).

Feedback produces higher bandwidths by **reducing** the gain at low frequencies. It trades gain for bandwidth.

Feedback makes the time response faster by a factor of $1 + \beta K_0$ ($K_0 = 2 \times 10^5$).

$$s(t) = \frac{K_0}{1 + \beta K_0} (1 - e^{-\alpha(1 + \beta K_0)t}) u(t)$$

$$\frac{K_0}{1 + \beta K_0} \frac{s(t)}{\beta = 1}$$

$$\beta = 0$$

$$t \text{ [seconds]}$$

Feedback produces faster responses by **reducing** the final value of the step response. It trades gain for speed.

Step response

The maximum rate of voltage change $\left. \frac{ds(t)}{dt} \right|_{t=0+}$ is not increased.

Feedback improves performance parameters of op-amp circuits.

- can extend frequency response
- can increase speed

Performance enhancements are achieved through a reduction of gain.

We wish to build a robot arm (actually its elbow). The input should be voltage v(t), and the output should be the elbow angle $\theta(t)$.

$$v(t) \longrightarrow \begin{array}{c} \text{robotic} \\ \text{arm} \end{array} \longrightarrow \theta(t) \propto v(t)$$

We wish to build the robot arm with a DC motor.

$$v(t) \longrightarrow \mathsf{DC} \text{ motor} \longrightarrow \theta(t)$$

This problem is similar to the head-turning servo in 6.01!

$$v(t) \longrightarrow \mathsf{DC} \text{ motor} \longrightarrow \theta(t)$$

- 1. $\theta(t) \propto v(t)$
- 2. $\cos \theta(t) \propto v(t)$
- 3. $\theta(t) \propto \dot{v}(t)$
- 4. $\cos\theta(t) \propto \dot{v}(t)$
- 5. none of the above

What is the relation between v(t) and $\theta(t)$ for a DC motor?

To first order, the rotational speed $\dot{\theta}(t)$ of a DC motor is proportional to the input voltage v(t).

First-order model: integrator

$$V \longrightarrow \gamma A \longrightarrow \Theta$$

$$v(t) \longrightarrow \mathsf{DC} \text{ motor} \longrightarrow \theta(t)$$

- 1. $\theta(t) \propto v(t)$
- 2. $\cos \theta(t) \propto v(t)$
- 3. $\theta(t) \propto \dot{v}(t)$
- 4. $\cos\theta(t) \propto \dot{v}(t)$
- 5. none of the above

Use proportional feedback to control the angle of the motor's shaft.

The closed loop system has a single pole at $s = -\alpha\beta\gamma$.

As α increases, the closed-loop pole becomes increasingly negative.

Find the impulse and step response.

The system function is $\frac{\Theta}{V} = \frac{\alpha \gamma}{s + \alpha \beta \gamma} \, .$

The impulse response is

$$h(t) = \alpha \gamma e^{-\alpha \beta \gamma t} u(t)$$

and the step response is therefore

$$s(t) = \frac{1}{\beta} \left(1 - e^{-\alpha\beta\gamma t} \right) u(t).$$

The response is faster for larger values of α . Try it: Demo.

The speed of a DC motor does not change instantly if the voltage is stepped. There is lag due to rotational inertia.

First-order model integrator

Second-order model integrator with lag

Step response of the models:

Analyze second-order model.

For second-order model, increasing α causes the poles at 0 and -p to approach each other, collide at s = -p/2, then split into two poles with imaginary parts.

Increasing the gain α does not increase speed of convergence.

Feedback and Control: Summary

- CT feedback is useful for many reasons. Today we saw two:
- increasing speed and bandwidth
- controlling position instead of speed

Next time we will look at several others:

- reduce sensitivity to parameter variation
- reduce distortion
- stabilize unstable systems
 - magnetic levitation
 - inverted pendulum
