## Introduction to Discrete-Time Systems

- Linear filters will not handle outliers very well - they are interpreted as impulses
- First defense against outliers: find out their origin and eliminate them at the beginning!
- Detection: Exceeding a known, fixed bound, or an impossible deviation from previous values. Example: vehicle speed >> the possible value given thrust level and prior tests.
- Second defense: set data to NaN (or equivalent), so it won't be used in any calculations.
- Third defense: try to fill in.

Example:

$$
\text { if } \begin{gathered}
\operatorname{abs}(x(k)-x(k-1))>M X, \\
x(k)=x(k-1) ;
\end{gathered}
$$

end;
Can get lost if multiple outliers occur!

## Time Resolution in Sampled Systems

- The Sampling Theorom shows that the highest frequency that can be detected by sampling at frequency $\omega_{\mathrm{s}}=2 \pi / \Delta \mathrm{t}$ is the Nyquist rate: $\omega_{\mathrm{N}}=\omega_{\mathrm{s}} / 2$.
- Higher frequencies than this are "aliased" to the range below the Nyquist rate, through "frequency folding." Includes sensor noise!
- The required rate for "visual" analysis of the signal, and phase and magnitude calculation is much higher, say ten samples per cycle.

## Filtering of Signals in Discrete Time

Use good judgement!

- filtering brings out trends, can reduce noise, but
- filtering obscures some properties of the signal

Causal filtering: $\mathrm{x}_{\mathrm{f}}(\mathrm{t})$ depends only on past measurements appropriate for real-time implementation
Example: $x_{f}(t)=(1-\varepsilon) x_{f}(t-\Delta t)+\varepsilon x(t-\Delta t)$
First-order lag, backward Euler
Acausal filtering: $\mathrm{x}_{\mathrm{f}}(\mathrm{t})$ depends on past and future measurements - appropriate for post-processing Example: $x_{f}(t)=[x(t+\Delta t)+x(t)+x(t-\Delta t)] / 3$

Moving window, centered, uniform weighting

A first-order filter transfer function in the freq. domain:

$$
\left.\mathrm{x}_{\mathrm{f}} \mathrm{j} \omega\right) / \mathrm{x}(\mathrm{j} \omega)=\lambda /(\mathrm{j} \omega+\lambda)
$$

At low $\omega$, this is approximately 1 ( $=\lambda / \lambda$ )

At high $\omega$, this goes to 0 magnitude, with 90 degrees phase lag $(\lambda / \mathrm{j} \omega=-\mathrm{j} \lambda / \omega)$

Time domain equivalent:

$$
d x_{f} / d t=\lambda\left(x-x_{f}\right)
$$

In discrete time, try this quick algorithm:

$$
\begin{gathered}
\mathrm{x}_{\mathrm{f}}(\mathrm{k})=(1-\lambda \Delta \mathrm{t}) \mathrm{x}_{\mathrm{f}}(\mathrm{k}-1)+ \\
\lambda \Delta \mathrm{t} \times(\mathrm{k}-1)
\end{gathered}
$$

SNR: 0.25, FFiltering at 20 and 60 Samples Rise Time

Thinking about discrete-time signals: time step $\Delta t$ between $\mathrm{x}_{\mathrm{k}}$ and $\mathrm{x}_{\mathrm{k}-1}$

Example:

$$
\mathrm{dx} / \mathrm{dt}=\mathrm{u}
$$

Fourier Transform: $\quad \mathrm{j} \omega \mathrm{X}(\mathrm{j} \omega)=\mathrm{U}(\mathrm{j} \omega)$

$$
X(j \omega) / U(j \omega)=1 / j \omega
$$

Let $q$ be the delay operator: q-transform: $\mathrm{X}(\mathrm{q})=\sum_{0}^{\infty} \mathrm{x}_{\mathrm{k}} \mathrm{q}^{-\mathrm{k}}$ This means: $X(q)=x_{0}+x_{1} q^{-1}+x_{2} q^{-2}+\ldots$

Make a discrete-time approximation for the example:

$$
\begin{aligned}
\mathrm{dx} / \mathrm{dt}=\mathrm{u} \rightarrow & \left(\mathrm{x}_{\mathrm{k}}-\mathrm{x}_{\mathrm{k}-1}\right) / \Delta \mathrm{t}=\mathrm{u}_{\mathrm{k}-1} \\
& \mathrm{X}(\mathrm{q})(1-\mathrm{q}) / \Delta \mathrm{t}=\mathrm{q} \mathrm{U}(\mathrm{q}) \\
& \mathrm{X}(\mathrm{q}) / \mathrm{U}(\mathrm{q})=\mathrm{q} \Delta \mathrm{t} /(1-\mathrm{q})
\end{aligned}
$$

So $\mathrm{j} \omega=(1-\mathrm{q}) / \mathrm{q} \Delta \mathrm{t} \quad$ for this case backward Euler

$$
q=1 /(1+j \omega \Delta t)
$$

Try a different method:

$$
\begin{aligned}
\mathrm{dx} / \mathrm{dt}=\mathrm{u} \rightarrow & \left(\mathrm{x}_{\mathrm{k}}-\mathrm{x}_{\mathrm{k}-1}\right) / \Delta \mathrm{t}=\mathrm{u}_{\mathrm{k}} \\
& \mathrm{X}(\mathrm{q})(1-\mathrm{q}) / \Delta \mathrm{t}=\mathrm{U}(\mathrm{q}) \\
& \mathrm{X}(\mathrm{q}) / \mathrm{U}(\mathrm{q})=\Delta \mathrm{t} /(1-\mathrm{q})
\end{aligned}
$$

So $\mathrm{j} \omega=(1-\mathrm{q}) / \Delta \mathrm{t} \quad$ for this case forward Euler

$$
q=1-j \omega \Delta t
$$

Let's do a more careful job by using both old and new u's:

$$
\begin{aligned}
\mathrm{dx} / \mathrm{dt}=\mathrm{u} \rightarrow & \left(\mathrm{x}_{\mathrm{k}}-\mathrm{x}_{\mathrm{k}-1}\right) / \Delta \mathrm{t}=\left(\mathrm{u}_{\mathrm{k}}+\mathrm{u}_{\mathrm{k}-1}\right) / 2 \\
& X(\mathrm{q})(1-\mathrm{q}) / \Delta \mathrm{t}=\mathrm{U}(\mathrm{q})(1+\mathrm{q}) / 2 \\
& X(\mathrm{q}) / \mathrm{U}(\mathrm{q})=(1+\mathrm{q}) \Delta \mathrm{t} / 2(1-\mathrm{q})
\end{aligned}
$$

So $j \omega=2(1-q) /(1+q) \Delta t$
bilinear approximation

$$
q=(1-j \omega \Delta t / 2) /(1+j \omega \Delta t / 2)
$$

Translating an analog system into discrete-time, e.g., Digital Filtering and Control:
Example:
$\mathrm{dx} / \mathrm{dt}=-\mathrm{x}+\mathrm{u} \quad$ (low-pass filter with cutoff frequency $1 \mathrm{rad} / \mathrm{s}$ )
$\mathrm{X}(\mathrm{j} \omega) / \mathrm{U}(\mathrm{j} \omega)=1 /(\mathrm{j} \omega+1)$
Substitute the bilinear approximation:
$\mathrm{X}(\mathrm{q}) / \mathrm{U}(\mathrm{q})=(1+\mathrm{q}) /[(1+2 / \Delta \mathrm{t})+\mathrm{q}(1-2 / \Delta \mathrm{t})]$
$\mathrm{x}_{\mathrm{k}}=\left[-(1-2 / \Delta \mathrm{t}) \mathrm{x}_{\mathrm{k}-1}+\mathrm{u}_{\mathrm{k}}+\mathrm{u}_{\mathrm{k}-1}\right] /(1+2 / \Delta \mathrm{t})$
Pseudo-code: It's ready to go!
Fact: TF’s X(j $\omega$ ) / U(j $\omega$ ) and $\mathrm{X}(\mathrm{q}) / \mathrm{U}(\mathrm{q})$ have almost the same magnitude and phase plots vs $\omega$ when $\mathrm{q}=\mathrm{e}^{-\mathrm{j} \omega \Delta t}$ (up to the Nyquist rate)

Consider vector case: $\quad \mathrm{d} \underline{x} / \mathrm{dt}=\mathrm{A} \underline{x}, \quad \underline{x}(0)=\underline{x}_{0}$
Solution must satisfy

$$
\mathrm{d} \underline{x}(0) / \mathrm{dt}=\mathrm{A} \underline{x}_{0} \text { and } \underline{x}(0)=\underline{\mathrm{x}}_{0}
$$

Solution is

$$
\underline{\mathrm{x}}(\mathrm{t})=\mathrm{e}^{\mathrm{At}} \underline{\mathrm{x}}_{0}
$$

where the $\mathrm{e}^{\text {At }}$ is a matrix exponential, obeying many of the rules of the scalar exponential:

$$
\begin{array}{ll}
\mathrm{d}\left(\mathrm{e}^{\mathrm{At}}\right) / \mathrm{dt}=\mathrm{Ae} \mathrm{e}^{\mathrm{At}} & \mathrm{e}^{\mathrm{At}}=\mathrm{I}+\mathrm{At}+\mathrm{A}^{2 \mathrm{t}} / 2!+\ldots \\
\mathrm{e}^{0}=\mathrm{I} \quad \text { (identity) } & \text { etc } \ldots
\end{array}
$$

Consider the system $\quad \mathrm{d} \underline{x} / \mathrm{dt}=\mathrm{A} \underline{x}+\mathrm{Bu}$ $e^{A t} B$ is the impulse response of the system such that

$$
\begin{aligned}
& \underline{\mathrm{x}}(\mathrm{t})=\mathrm{e}^{\mathrm{At}} \underline{\mathrm{x}}_{0}+\int_{0}^{\mathrm{t}} \mathrm{e}^{\mathrm{A}(\mathrm{t}-\tau)} \mathrm{Bu}(\tau) \mathrm{d} \tau \quad \text { OR } \\
& \underline{\mathrm{X}}_{\mathrm{k}}=\mathrm{e}^{\mathrm{A} \Delta \mathrm{t}} \underline{\mathrm{X}}_{\mathrm{k}-1}+\int_{\mathrm{tk}-1}^{\mathrm{tk}} \mathrm{e}^{\mathrm{A}(\mathrm{tk}-\tau)} \mathrm{Bu}(\tau) \mathrm{d} \tau
\end{aligned}
$$

Let $u$ be constant on $t_{k-1}$ to $t_{k}$ (zero-order hold):

$$
\begin{array}{lr}
\underline{\mathrm{x}}_{\mathrm{k}}=\mathrm{e}^{\mathrm{A} \Delta \mathrm{t}} \underline{\mathrm{x}}_{\mathrm{k}-1}+\int_{\mathrm{tk}-1}^{\mathrm{tk}} \mathrm{e}^{\mathrm{A}(\mathrm{tk}-\mathrm{t})} \mathrm{d} \tau \mathrm{~B} \mathrm{u}_{\mathrm{k}-1} \\
\underline{\mathrm{x}}_{\mathrm{k}}=\Phi \underline{\mathrm{x}}_{\mathrm{k}-1}+\Gamma \mathrm{u}_{\mathrm{k}-1} & \text { 1:1 mapping between continuous and } \\
\text { discrete-time systems }
\end{array}
